The construction of the "Duyfken replica," a reconstruction of a Dutch *jacht* of appropriate date (early seventeenth century) and size, was an opportunity to test the practicality and effectiveness of the Dutch system of plank-first construction. The idea that the European age of discovery and subsequent domination of much of the world's maritime trade was made possible, in part, by the switch to frame-first construction of ships is undermined by the Dutch retention of plank-first construction at a time when Dutch shipping was superior to that of the rest of Europe in terms of tonnage, volume of cargoes carried, and successful execution of the long voyages to and from East Asia. The Duyfken replica has made long voyages demonstrating maneuverable and seaworthy performance.

Extreme Environments Archaeology: Climate

Vivian Scheinsohn
Instituto Nacional de Antropología y Pensamiento Latinoamericano-Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET)/Universidad de Buenos Aires, Facultad de Filosofía y Letras, Buenos Aires, CABA, Argentina

Introduction

There is no complete agreement on how to define an extreme environment. The term is frequently used for any setting that exhibits life conditions unfavorable or fatal to certain organisms with respect to its physicochemical properties. Major classes of extreme environments include acidic (pH < 5), alkaline (pH > 9), hypersaline (salinity $>35\%$), pressurized (>0.1 MPa), hot (>40 °C), cold (<5 °C), dry (aw < 0.80), and high-radiation environments (Thiel 2011). They can be natural and/or artificial, permanent, episodic, or temporary. Hence, an environment could be extreme or not, depending on the organism implied and the physical boundaries within which they can thrive. Since humans are terrestrial, subtropical, air-breathing, low-altitude homeotherms (Cotter and Tipton 2014), most of the world represents a challenge for us. Given that 2/3 of the world is covered by oceans and humans are not biologically aquatic animals, we have to focus on the remnant terrestrial third to find out our ideal environment. If in that third, we look for climate and topography temperate enough for the kind of subtropical primate we are, we will keep only one-sixth of the planet (Piantadosi 2003). This leaves us with a narrow part (see shadowed area in Fig. 1). Consequently, it is logical to think that we humans had to overcome our limitations, if not by natural means at least by cultural ones, in order to multiply and prosper. Cultural adaptations, ultimately, allowed us to inhabit not only extreme climate regions but also, more recently and for limited amount of time, even the outer space. Having acknowledged the wide variety of extreme environments that exist, in the rest of this article, we will deal only with arid, cold, and high-altitude environments. Also just as climatic extremes can be spatial, they can also be temporal. In this latter case, we speak of extreme events. They include droughts, floods, wet periods, warm periods, cool periods, and high-variance periods. But since they are unpredicted and there are no widespread conventions for how these events are defined, we will not refer to these events in this entry (but check cross-references for more on this subject).

Definition

The range of body temperatures compatible with human life is relatively narrow and contrasts with the wide climatic variability that the Earth shows. The first quantitative classification of world climates was elaborated by Wladimir Köppen. As a plant physiologist, he had differentiated five vegetation groups including plants of the equatorial zone (A), the arid zone (B), the warm temperate zone (C), the snow zone (D), and the

E

Extreme Environments Archaeology: Climate, Fig. 1 World map with the area between the isotherms of 10 °C and 20 °C shadowed. Credit: Ana Fondebrider

polar zone (E). A second letter in the classification considers the precipitation and a third letter the temperature (e.g., Dfc for snow, fully humid with cool summer; see Kottek et al. 2006). Hence, there exist at least 31 types of climates (Kottek et al. 2006).

As said above, extreme is a relative term but habitats are multidimensional. Hence while some habitats could be considered extreme in terms of mean temperature, they can have other features judged to be favorable. For instance, if we consider as extreme climate the ones in which the mean annual temperature is either less than 10 °C or above 20 °C (not shadowed area in Fig. 1), we can see that most of the world falls under this category. Nevertheless altitude, topography, precipitation, latitude, continentality, and oceanity are factors that should be contemplated. In that sense, other measures such as effective temperature, a concept designed by Bailey (1960) that Binford (1980, 2001) has utilized as an operational definition of growing season, could be a more synthetic way of establishing extreme environments.

Historical Background

From the nineteenth century on, we can consider that archaeology has been established as a discipline. Since its onset, climate was important in its development. First, the direct experience of - climate during fieldwork suggested to the first archaeologists the importance of climate in human life, past and present. But also, climate began to be part of different theoretical frameworks, which considered it as conditioning or even determinant. After World War II, recognition of the environmental effects increased, and archaeologists were of the first to provide evidence of environmental disasters generated by humans that ultimately led to abandonment of sites or the collapse of political systems (Dean 2015). Possibly this awareness allowed Julian Steward's ecological perspective to emerge. Steward

(1955) advocated that anthropologists should understand each culture in its ecological context, giving rise to cultural ecology (Dean 2015). Since then, climate change has been proposed as one of the prime movers for explaining social change. Cultural ecology eventually influenced processual archaeology, the dominant theoretical movement of the 1960s and 1970s in the USA. One of its founders, Lewis Binford, in his monumental analysis of hunter-gatherer behaviors in a global scale, defined environmental variables as his frame of reference (Binford 2001: 50).

Also it should be noticed that environment and climate have been related with the level of complexity that certain societies could achieve. For instance, Diamond (1997) has proposed that societies developed in a different way on different continents because environmental differences. Complex societies could emerge only in dense sedentary populations capable of accumulating food surpluses, and they depended on the rise of agriculture for doing so. But domesticable wild plant and animal species were distributed very unevenly and concentrated in only nine areas of the globe, which thus became the earliest homelands of agriculture (Diamond 1997: 100). Some of those homelands are located in what we can consider arid (and hence extreme) regions (see below).

Given the importance of climate for archaeological theory in general, it is strange that extreme climates did not achieve special attention until very recently. In the review volume of *American Antiquity* in which a group of archaeologists identified the 25 grand challenges that archaeology has to face, among them figured how do humans occupy extreme environments and what cultural and biological adaptations emerge as a result (Kintigh et al. 2014). This means that although certain international efforts are beginning to gain momentum (see below), the archaeology of extreme environments is still rising.

Key Issues/Current Debates

Arid Environments

Aridity could be defined as a deficit of moisture in the environment. But aridity is a complex concept, and its environmental manifestations vary from place to place and through time. Although aridity is equated normally with deserts (defined as an area with a moisture deficit where rainfall is less than 20% of potential moisture loss through evaporation; see Smith et al. 2005), there is a great diversity within, and between, arid environments going far beyond deserts (Thomas 2011: 3).

Deserts cover around 25,500,000 km^2, approximately 20% of the terrestrial world, being present in both Northern and Southern Hemispheres. They present patchy, variable, and frequently unpredictable resources. Therefore, patches where water is available are key to human exploitation, providing access to the arid hinterland and means of traversing the land like navigating through "islands on the sea" (cf. Veth 1993). For humans, arid environments could be areas to avoid, but they are also environments that can be successfully exploited. Lack of surface water, limited food, and climatic extremes have generally made think that arid areas are unfavorable places for habitation, though hunter-gatherer and pastoral-nomadic peoples, living at low population densities, managed to thrive there (Thomas 2011).

Archaeological evidence indicates that people have a long presence in African deserts. Early Stone Age or Acheulian sites are reported from the Namib, Kalahari, and the eastern Sahara, but it is not clear whether this reflects exploitation of certain patches within an arid environment or whether these areas were semiarid savannas at that time (Smith et al. 2005). In Australia, the most arid continent ever occupied by humans (Veth et al. 2015), groups entered Sahul c. 50,000 years ago in favorable conditions. In what has been labeled the "desert transformation model," groups first adapted to more benign climates and, given shifting conditions, have to made changes in their settlement behavior, technology, economy, etc. (Veth et al. 2015). Prehistoric population grew slowly until the Last Glacial Maximum, when evidences of abandonment of large parts of the arid interior, population decline, and surviving populations retreating at refugia are recorded (Veth et al. 2015). By the time Europeans arrived in Australia, the deserts were more densely packed, a process that, in

the late Holocene, produced the desert societies known by early ethnographers (Veth et al. 2015).

In the Americas, human exploration and colonization of deserts occurred very early in terms of its peopling: either in South (around 12,000 years BP; see Borrero 2015) and in North America (around 11,000 BP although settlement probably did not occur until early Archaic; see Smith et al. 2005).

Arid regions of the world have a special role in human evolution. They have funneled early human dispersal, representing alternatively barriers or corridors (Smith et al. 2005). Some of them, showing more favorable conditions, had allowed the domestication of plants and animals (cf. Diamond 1997). And also studies of desert societies have provided the most fertile debates about human adaptability, how societies cope with extreme environments, and their effects on human land use, mobility, and dispersal (Smith et al. 2005).

Cold Environments

Humans tolerate cold quite poorly compared to other mammals. Survival in the cold is limited primarily by hypothermia, defined by a core temperature of less than 35 °C (95 °F) when body's defenses against cold (shivering and constriction of blood vessels) reach maximal response. If the body cools further, at 30 °C (86 °F), shivering ceases, and at 27–29 °C (80–85 °F), coma occurs. Hence, people can only survive in cooler climates by behavioral adaptations, which include wearing clothing, building shelters, and maintaining sources of external heat (Piantadosi 2003).

Since the first use of fire, dated as early as 800,000 years ago (Walker et al. 2016), people have regulated the temperatures of their dwellings. While fire and shelter facilitated hominin presence in cooler climates, only the use of clothes, an efficient and flexible strategy to stay warm, could sustain occupation of cold climates (Gilligan 2016). There is archaeological evidence indicating that hominins began to use simple clothes (animal skins and furs) by Middle Pleistocene. Scrapers to work hides became more frequent in middle latitudes as hominins occupied colder environments from 400,000 years ago (Gilligan 2016). These northern and colder areas were abandoned during the peak of the Last Glacial Maximum (LGM, 20,000–18,000 years ago). But only the development of complex clothes (fitted garments with the option of multiple layers, Gilligan 2016) allowed the occupation of the Arctic. Complex clothes required new tools such as stone blades, bone awls, and bone-eyed needles developed first in Africa during a cold phase (75,000–60,000 years ago; Gilligan 2016). These tools and clothes accompanied modern humans when they spread into northern Eurasia (45,000–25,000 years ago) and explored Siberia during the climatic amelioration following LGM (Rogers and Anichtchenko 2015). Complex clothing gave to *Homo sapiens* an advantage over Neanderthals (whose scraper-dominated toolkits suggest they had only simple clothes, Gilligan 2007) and finally, along with technologies related with maritime subsistence such as skin boats and toggling harpoons (Rogers and Anichtchenko 2015), facilitated the occupation of the Arctic.

In the Americas, the oldest archaeological sites in Alaska date to c. 15,000 BP, and by c. 4500 BP, Paleo-Eskimo peoples had settled in North Greenland (Rogers and Anichtchenko 2015). The most recent human occupation of extreme cold climate was that of the Antarctica which occurred very recently (since all Antarctic archaeology is historical archaeology) being brief, infrequent, and scattered (Pearson and Senatore 2015).

High-Altitude Environments

High-altitude environments are defined as those at and over 2500 m above sea level (Aldenderfer 2015). It has been estimated that 150 million people live permanently at high altitude. Most of these permanent high-altitude residents live in the Andes between 2700 and 4500 (9000 and 15,000 ft; Piantadosi 2003). Physiological adaptation to hypoxia (low oxygen density) was critical for the establishment of permanent habitation at elevations above 2500 m. This adaptation (based upon selection for alleles identified as promoting improved oxygen transport) probably took some time in developing (Aldenderfer 2015) acting as a constraint on the earliest inhabitants of these environments. Also at

high elevations, even in tropical mountains, cold is a constant problem (see above). The combination of cold, hypoxia, and aridity creates a context of low primary productivity in which high-altitude inhabitants has to survive (Aldenderfer 2015).

Although evidence for the occupation of high-altitude environments is relatively recent in human history, it is possible that some of our hominid ancestors may have used zones above 2500 masl (as the southern margin of the Ethiopian plateau) as early as 1.5 mya (Aldenderfer 2015).

In South America, highland occupation appears after 10,500 BP, a very early occupation taking into account South American peopling (although there is controversial evidence of earlier sites; see Dillehay 2000; Aldenderfer 2015). It was initiated by foragers moving from low-elevation sites into the Andean highlands to procure resources such as obsidian and animals (Aldenderfer 2015). Some of the high-altitude environments of the Puna of the South-Central Andes witnessed the early Holocene process of domestication of camelids (Yacobaccio 2007; Mengoni Goñalons 2008), a process related with year-round occupations (Borrero 2015). Aschero (2000) suggested that Puna occupation may have optimized the use of resources from Puna (highlands), *quebradas* (canyons) and valleys located at different altitudes. Resources from valleys and forests were recorded in various archaeological Puna sites, in spite of the lack of sites in those areas where these resources came from (Aschero 2000).

In Asia, although there has been speculation that the Tibetan Plateau was occupied as early as 50,000 years ago, more recent research suggests that it is no earlier than 30,000 years ago and could be much later in time (Aldenderfer 2015; Borrero 2015).

Hence, although it is probable that humans made seasonal forays into high-elevation environments perhaps from the Lower Paleolithic, the permanent occupation of high-elevation environments occurred relatively late. The adoption and spread of plant and animal cultigens, along with acquired genetic adaptations, allowed high-elevation inhabitants to create complex polities (Aldenderfer 2015).

International Perspectives

As extreme environments are distributed all over the world, they have been archaeologically researched in different countries, but they have not been considered in a global scale. Some efforts are conveyed right now in order to amend this need.

At the Southern Hemisphere, the Southern Deserts Conference has given a new impulse to desert archaeology. It is an interdisciplinary meeting that promotes a comparative perspective on the Quaternary evolution of desert landscapes and peoples from the Southern Hemisphere (Oceania, Africa, and South America). It proposes a fluid dialogue between paleoecology, geology, and archaeology. Four successful conferences had been held: Canberra (Australia, 2003), Arica (Chile, 2005) Kalahari (South Africa, 2008), and Uco Valley (Argentina 2014). Also the ICOMOS International Polar Heritage Committee had very recently constituted a Polar Archaeology Working Group which held its first meeting at 2017.The purpose of the PAWG is to work toward developing and delivering a set of principles for polar archaeology, with best practice guidelines to subsequently be developed. Finally archaeologist Brian Stewart is working to develop a comparative focus group on high-altitude archaeology. Hopefully, in the future, more international-scale efforts directed to extreme environments will be developed.

Future Directions

The archeology of extreme environments is still in early stages of development, probably because of the challenges that extreme climate-related environments posed to archaeology. Technical advances, as new and cheaper means of transports and even drones, should facilitate fieldwork. But in some countries, to afford these new technologies makes climate-related extreme environment archaeology prohibiting. More international conferences and networks are needed to overcome the research challenges of unequal national research funding. Archaeological research in extreme environments

offers the opportunity to test theories of cultural adaptation at the limits of viability. Its need is evident, and today we have the best conditions ever to accomplish it.

Extreme Environments in Archaeology: Disaster

Eduardo Corona-M and María Isabel Campos Goenaga
Centro INAH Morelos, Instituto Nacional de Antropología e Historia, Cuernavaca, Morelos, Mexico

Introduction

Historically, the so-called "natural disasters" have been considered an important study object among archaeologists, such as the case of the renowned localities of Pompeii and Herculaneum (Italy), excavated since the eighteenth century. However, the explanation of the disaster has increased throughout the twentieth century, since it has been invoked as the cause of various social transformations, especially because of their effects on complex societies (Sheets 1980; Buren 2001). Currently, it is also claimed that natural hazards and disasters are among the great challenges of twenty-first century archaeology by the growing interest on this issue (Kintigh et al. 2014; d'Alpoim Guedes et al. 2016).

However, it is noteworthy that archaeology does not have yet a complete documentation regarding localities, theoretical and methodological approaches, or disciplinary collaborative agreements. Unlike what it has been done from the anthropological and historical perspective (Brown 2017), where various natural phenomena have been documented in a long chronology, such as: El Niño/La Niña events; droughts, hurricanes, earthquakes, floods, vulcanisms, among others. The aim of this work is reviewing the protocols for the study of disasters from an archaeological perspective and the impulse that has received from other disciplines, for its characterization and explanation.

Definition: The Disaster Is Social and the Phenomenon Is Natural

Human populations on the planet have colonized and occupied a diversity of environments, from the tundra and the desert to the tropical forests, arising a large diversity of economies going from the hunter-gatherers to the most sophisticated urban populations. All of this produces a great cultural diversity and generate a myriad of attitudes toward to nature (Ramos Roca and Corona 2017; Cooper and Sheets 2012). Then, in human and nature relationships, nothing is static, everything is constantly changing, but also some aspects have persistence. The relationship that societies establish with nature is seen at the same time as an ideological perspective, material reality, and scenario of human activity, where is an increased concern about the dangers of sudden environmental changes or the presence of episodic events that affect them (Arnold 1996; Cooper and Sheets 2012). A central element in the analysis of these phenomena is the tension that exists between the natural and the cultural, since this defines the role of each of them in the social construction of risk, in the accumulation of vulnerability or in the disaster itself. Natural phenomena are described according to the scale of affectation, the location and its area of influence. That is, they can be classified according to their etiology, but also by their scale, in episodic and short- or long-term events (Cooper and Sheets 2012; García Acosta 2005).

Because of its scale, short-term events are related to changes in climate and seasonality, but also to biological events, such as pests and epidemics, would also be located; while the long-term ones are linked mainly to temperature, such as changes in marine currents that affect climate (El Niño/La Niña event), desertification, and environmental erosion, among others. On all of them, societies tend to adapt, but also affect the soils, flora, and fauna, sometimes irreversibly, so that

can lead to profound changes in populations and societies, which also increases the risk survival. Others are episodic, high-energy events that affect landscapes and human populations, such as: volcanism, earthquakes, hurricanes, droughts, frosts, uncontrolled fires, and floods. Finally, another category of dangers may be related to a natural event, but they are more linked to management from the social sphere, such as famines, arson, and social conflicts, including war, which increase both levels of human mortality, as well as those of environmental impact (Cooper and Sheets 2012).

This type of studies considers two premises: societies are not passive recipients of a phenomenon or natural event, therefore, the interaction between society and phenomenon must be considered, characterizing each of them specifically. The episode or incidence of an adverse natural phenomenon is accompanied by other social, political, economic, and cultural facts, which must be assessed to understand the phenomenon and its context, determining its scope, results, and consequences.

For archaeology, that usually has incomplete and interpretative evidence, it can start from the basic proposal to characterize a disaster, which is summarized in Table 1.

Extreme Environments in Archaeology: Disaster, Table 1 Basic characteristics of natural disasters (after Shimoyama in Torrence and Grattan 2002)

Characteristics	Definition
Initiation	The original process or event that set the scene for the disaster, e.g., extreme natural events such as volcano, flood, earthquake, and tsunami
Immediate causes	Specific aspects of the event, which have direct effects on human life and property
Local conditions	Natural and sociocultural variables that establish the local setting at the time of the event
Damages	Concrete negative effects
Assessment	Process in which victims and observers assess the extent and repercussions of the damages
Actions	Acts carried out following the disaster. These include both short-term actions, such as abandonment and cleaning up, etc., and long-term adaptations, such as moving to a new area, collapse of social system, institution of preventive measures, adoption of ritual practices to avoid further occurrence of disasters, etc.

Natural events can be triggers of a disaster or are threats when they are considered risk agents, based on the probability that it manifests itself in a period of time and in a specific site. Therefore, a risk equation must integrate both the threat and vulnerability, understood as the inability of a human community to respond adequately to the phenomenon. Consequently, disaster, although linked to a natural phenomenon, has a character and a social definition, which must be explored and understood as a whole (Torrence and Grattan 2002; García Acosta 2005).

Historical Background: Key Issues/ Current

Although studies on natural phenomena have been recurrent in geography, geology, and other physicochemical and natural disciplines, they considered the societies as passive elements facing the power of nature. In the 1980s, the "alternative model" emerged (Maskrey 1993), which represented the most important effort made up to the moment, in order to integrate a social theory about disasters. This was the first text that systematically presented a radical and integral critique of the dominant physicalist paradigm. Hewitt's essay was decisive in locating vulnerability, not only as a feature of different threats but, above all, originated by economic, political, and social processes (Buren 2001).

From this, we know, but do not follows, the perspective that addresses the archeology of the disaster, such as that dealing with the urgent requirements of identification of victims and research scenarios, after mass death events, since they were considered more linked to forensic processes (Gould 2013; Harrison 2016).

From the anthropology, it was observed then that there are disasters with a long-term development, those that are manifested after a sustained cultural use of the environment, produced by the population growth and the landscape modification, where some cases are: the urbanization

processes, the impact of the infrastructure, the systems of social organization, all of them inserted in the relation of the societies with the environment. At the beginning, researchers proposed that disasters were "natural" and privileged their study in "high-risk societies," establishing an equation, where the disaster is equal to the risk of occurrence of a phenomenon due to the vulnerability of the affected society. Currently, the concept of risk and its management are linked, so that the disaster is definitely located in the social sphere, which are influenced as much by the threats, i.e., the physical events that may happen, as well as for vulnerability (Maskrey 1993).

In the 1990s, there is the "vulnerability approach" or "vulnerability paradigm," which makes the analysis of disasters explicit from the perspective of the families and human communities involved. Then, the historical evidence shows that the risk and disaster are multidimensional and multifactorial processes, which is the result from the association between threats from natural phenomena and certain conditions of vulnerability, which are built and reconstructed over time (Blaikie et al. 1994).

From an archaeological perspective, then it must be considered that natural phenomena have an important role as a trigger of a disaster, but they are not the cause. This is of multiple nature and is found more in the socioeconomic and environmental characteristics of the impacted region (Van Buren 2001; Campos Goenaga 2016; Cooper and Sheets 2012).

Debates

The study of disasters and natural phenomena is in principle multidisciplinary, involving fields, such as meteorology, geology, and geography, and includes social sciences, such as anthropology and psychology, but up to the end of the twentieth century, they did not have a paradigm in common and each one emphasized some particular natural, social or cultural aspects. Buren (2001) highlights that geography was one of the disciplines where disaster research was developed and of great influence in archaeology, for the emphasis on human populations; however, it had a greater biases and funding towards the technological and physical science aspects, in general, aspects that are related to the economic-industrial impact that these activities could generate, an were debated at these time (Buren 2001).

Perhaps the most complicated issue is how archaeology could characterize and explain the disaster from a social perspective. There are several examples where, although a series of hazard events are documented, but the effects on the populations that inhabited the region are not investigated, as can be observed on volcanism in Central America (Torrence and Grattan 2002) and México (Barrera Rodriguez 1997); floods, plagues, and other events in the European Middle East (Brown 2017); earthquakes, tsunamis, and coastal subsidence in the American Northwest (Losey 2005). In most of all of those cases, a prediction menu was assumed for the situation of the human populations: the destruction of the settlements, the migration, and in the best scenario the adaptation and the environmental resiliencies, with which an image of cultural stability was offered. The prevailing hypothesis was that "simple" societies seemed to be more resilient than complex societies, since the latter relied on a built environment and economies based on labor specialization, redistribution, and extensive trade routes (Torrence and Grattan 2002).

It appears that the researchers concentrated on particular cases of episodic phenomena, which were commonly assigned as "disasters" because their inhabitants could not be facing nature. Therefore, a diversity of variables and situations were omitted, especially with regard to the long-term effects of the event and the possibilities of recovering the environment, human populations, the settlements, and particular habitat that constitutes their environment. It even obscures the discussion about the particularities of the natural event that triggered the disaster, for example, the intensity of the earthquakes, the scope of volcanism, which today anthropology has shown to be key parts to understand as part of the equation that includes vulnerability, risk and disaster itself (Torrence and Grattan 2002; García Acosta 2005; Campos Goenaga 2016).

The methodological aspect is one of the most developed in recent years, where it has been

observed the effectiveness of incorporating various sources to analyze these human-nature interactions, considering that archaeology should have the tools for the study of social decline and collapse, since that long-term chronologies could be achieved, and are a central part of the archaeological record. In most cases, where in the absence of written materials, the material remains of societies and stratigraphic contexts are evidences most important to study these phenomena (Brown 2017).

However, the practice to retrieving environmental and socials information through the revision of historical, ethnohistorical, and even ethnographic evidence is practically the most frequent and allows to establish long chronological sequences, related to changes of local or regional landscapes, sociocultural practices, impact and presence of episodic events or events biological as the presence of pests and epidemics. These aspects provide to archaeology with a series of alternative evidences to construct or discuss the hypotheses that are formulated regarding the study of natural phenomena and disasters (Torrence and Grattan 2002; García Acosta 2005; Campos Goenaga 2016.

In that context, an emerging discipline is archaeo-seismology, which although initiated as a "curiosity" collecting data on sources and contrasted with field data, became a multidisciplinary collective effort to obtain the greatest amount of information from ancient earthquakes records, which can be assessed by the growing number of catalogues and the regional and intensity information contained in each one of them. In some cases, this information is the basis for establishing regional cultures for the prevention of earthquake damage (Sintubin 2011).

International Perspectives: What Is the International View From Where the Author Is?

In the light of above process and discussions, various scholars interested in promoting interdisciplinary research have emerged, promoting collaborations with colleagues from the physical-natural fields and the social sciences, either through periodic academic events or establishing research networks.

One of the first experiences in Latin America was the *Red de Estudios Sociales en Prevención de Desastres en América Latina* (Social Studies Network on Disaster Prevention), which work from 1992 to 2015 (http://www.desenredando.org/). Another one with mainly Ibero-American scope and influence is the *Red Temática de Estudios Interdisciplinarios sobre Vulnerabilidad, Construcción Social del Riesgo y Amenazas Naturales y Biológicas* (Thematic Network of Interdisciplinary Studies on Vulnerability, Social Construction of Risk and Natural and Biological Threats) (http://sociedadyriesgo.redtematica.mx/). Most recently was announced the work of the Global Human Ecodynamics Alliance (http://www.gheahome.org/).

These are some of the collective academic efforts that offer ongoing dialogue between researchers (Symposium, Congress, Seminars, Workshops), outreach actions (courses, brochures, articles, books, social networks, and mass media), as well as Internet portals for free access to written and multimedia files on all aspects related to risk, vulnerability, disasters, and, in general, perspectives on human-environment interactions.

These efforts are supported by international foundations, by public and private organizations, both at national and international levels. One of the most notable organisms is the United Nations Office for Disaster Risk Reduction (https://www.unisdr.org/), where it can be found an up-to-date statistics to measure risk and vulnerability in current societies. However, it is worth highlighting the limited and marginal collaboration of archaeology in this growing field of research.

Future Directions

The apparent dominance of humans over nature is daily tested, as populations are increasingly vulnerable to natural phenomena and disasters, among other causes due to the increased rate of population growth, the loss of habitats, and the

intensive use of natural resources, including the nonrenewable. In this context, it is reiterated that archaeology can make key contributions to the interdisciplinary study of the disaster in various aspects (Torrence and Grattan 2002; Cooper and Sheets 2012), here is commented some emerging and promising issues in the current literature.

One is filling the gap between salvage archaeology after a disaster, and its later contributions both to the recovery of the spaces of daily life prior to the disaster, and in the understanding of the symbols of loss and, in general, to collaborate in creating a collective memory (Bagwell 2009). A close collaboration with anthropologists and in general with civil and governmental organizations involved in the processes can be made.

The combination of geoscientific and archaeology studies could help to reinterpret the episodic natural phenomena of the past allows providing data and time series in the establishment of patterns that are useful for the establishment of public policies and for outreach processes (Riede 2017).

The archaeology could document the circumstances in which humans adapted to the particular environments that are generated by climatic changes. In several regions the data, however, may be scarce, so it is possible to alternately work in the construction of computational models that allow to recreate in a reliable way the environmental scenarios and thus establish more refined hypotheses about the adaptive strategies used by human populations (d'Alpoim Guedes et al. 2016). It should be noted that those models could be adjusted to include the variables referring to natural phenomena, especially in those regions that are susceptible to the presence of episodic phenomena, such as coasts, seismic, hydrographic, volcanic regions, among others.

Recognizing the importance that disasters and natural phenomena have had and have in the daily life of human populations, it cannot be ignored that these can also influence the survival of a series of symbolic elements, either sites or objects, several of them considered as cultural heritage, protected by local, regional or world-wide legislation. Development of methodologies to measure the vulnerability of these elements is important to establish measures of protection or mitigation of risks applied by civil or governmental agencies, responsible for the preservation of those sites (Minos-Minopoulos et al. 2017).

Since the study of disasters is located in the sphere of interactions between humans and the environment, this implies revising the theoretical aspects that allows clarifying its dynamics from other perspectives, especially if the humans were a particular element of the environment, belonging to the past and present biodiversity.

The human is also a species with a sophisticated scientific knowledge, that includes the so-called ethno-knowledge as part of the scientific thinking (Ramos Roca and Corona 2017; Fitzhugh et al. 2018). Then, the research from ethnobiological and biocultural spheres highlights the importance and influence of those local knowledge on the use of humanized landscapes at rural localities and how also that modifies the influence of globalization in the cities of the planet. That understanding of different perspectives may be necessary to address the complex problem of the disaster in a diachronic way, since that affects to all the biodiversity, but also to a particular species, which is human, and whose survival depends on their intuition and ability to dialogue. Our opportunity to continue the hominization process depends, perhaps, on our ability to continue understanding, and of build societies based on collective knowledge with quality of life and sustainable for the planet.

Eyo, Ekpo Okpo

Emuobosa Akpo Orijemie
Department of Archaeology and Anthropology, University of Ibadan, Ibadan, Nigeria

Basic Biographical Information

Professor Ekpo Okpo Eyo was an eminent Nigerian scholar of many parts known to people as an Archaeologist, art historian, and museologist. He was regarded as a giant pillar, on which the growth of Nigeria's museums, was establishment in Nigeria.

Ekpo Okpo Eyo was born on 28 July 1931 at Creek Town, Odukpani Local Government Area, of the present-day Cross River State, Nigeria. He began his early education at the Creek Town School and subsequently at the Duke Town

School, Calabar. His secondary education was at the Evening Secondary Continuing School, Calabar between 1937 and 1947. In 1960, he proceeded to the Institute of Archaeology, London, and Pembroke College, Cambridge University, where he spent the next three years (1960–63). It was at the Institute of Archaeology, London, that Eyo began to chart a path for the journey he was to take for life. However, it was in Ibadan that his intellectual maturity blossomed. Having obtained a B.A. (Cantab.) in Social Anthropology in 1963, and an M.A. (Cantab.) in 1967, he earned his Ph. D. in Archaeology in 1974 from the University of Ibadan, the first Nigerian to ever achieve this feat.

As a scholar, he garnered several awards including those received during his early years: School Prize in English and Mathematics at his Duke Town School, Calabar, in 1947; *Silver cup in Broadcasting* at the "All Nigeria Festival of the Arts" in 1956. The following year, he was awarded a Certificate in Conservation and Restoration of Archaeology and Ethnographical Specimens at the University of London in 1957. In 1962, he earned the Gordon Childe Prize for the best student of the year in Archaeology at the University. The same year, Professor Eyo was offered an associateship of the Museum Association of Great Britain and Ireland, and was awarded a Professional Diploma in Museology.

Major Accomplishments

He distinguished himself as the first and only Nigerian Director of the Federal Department of Antiquities (1968–1979), and first Director General (DG) of the National Commission for Museums and Monuments (NCMM) between 1979 and 1986. During his stint as a Director for 18 years, Ekpo Eyo laid the foundation of NCMM and made it a success. In the following years, Professor Eyo became an authority in Archaeological research, particularly African arts. His passions for archaeology and the arts were inseparable. It was once said that it was to the arts that he devoted more love and attention. However, Prof Eyo opined that it was Archaeology that opened his eyes to the arts. Thus, among the several positions he held, between 1963 and 1973, he was the President of the Museum Association of Tropical Africa (1963–73) and Vice President of the Advisory Council of the International Council of Museums (ICOM) (1965–74). Between 1976 and 1980, he became the chairman of the West African Archaeological Association; Vice Chairman of the World Heritage Committee of UNESCO; and Chairman, Organization of Museums, Monuments and Sites in Africa (OMMSA) from 1976 to 1978.

Ekpo Eyo: A Blend of Archaeology and the Arts

His passion for the arts was legendary that, Prof Ben Enwonwu, one of Nigeria's finest Artists, described him as a great man of Antiquities (Adaka 2012). This passion culminated in the exhibition "Treasures of Ancient Nigeria: Legacy of 2000 Years." It successfully put an end to the concept that the African continent lacked any civilization until contacts with Europe. The exhibition was a major instrument that made Nigeria more respected around the world. The exhibition was later to tour Britain, USA, and Canada between 1980 and 1986 (Archibong 2011). The exhibition had been published into a book, with the same title, coauthored by Frank Willet in 1980. Other books written by him included *2000 Years of Nigerian Art* and *From Shrines to Showcases: Masterpieces of Nigerian Art*.

After retirement from the NCMM, Eyo was appointed Professor of African Arts and Archaeology at the Department of Art History and Archaeology, University of Maryland, College Park, USA, in 1986. There he spent the latter part of his life researching and teaching. During this time, Professor Ekpo Eyo often carried out archaeological excavations in Calabar. One of the major results of these excavations was *The Terracottas of Calabar*, published in 2008. Professor Eyo published over 25 scholarly articles in learned journals and delivered about 30 lectures in museums and top universities in America Europe and Nigeria. He was, in 1975, admitted into the *"Ordre des Arts et des Lettres"* by the French

Government. In 1980, he bagged the Officer of the Federal Republic (OFR) award by the Federal Government of Nigeria. In 1989, he was conferred with an Honorary Degree of Doctor of Letters by the University of Calabar, Nigeria. Five years later, he was presented with the Art Council of African Studies Association (ACASA) Leadership Award at the 13th Triennial Symposium on African Art at Harvard University.

†On May 28, 2011, Professor Ekpo Okpo Eyo passed away in Maryland, USA, at the age of 80. A former Secretary General of the Commonwealth, Chief Emeka Anyaoku, said of him: "a true icon of Nigerian Archaeology, Anthropology and Museums, and an outstanding scholar of Nigeria's cultural heritage (Adaka 2012)." However, a succinct description of him was given by a former director of heritage, monuments, and sites in Nigeria that Prof Eyo, even in death, is "a priceless museum piece (Archibong 2011)."

F

Facial Approximation and Craniofacial Superimposition

Carl N. Stephan
Central Identification Laboratory, Joint POW/MIA Accounting Command, Joint Base Pearl Harbor-Hickam, HI, USA

Introduction

When concerns exist as to the identity of a set of remains and when DNA, dental, and radiographic comparisons are not possible, the morphology of the skull can be used in conjunction with the biological profile to help provide answers (İşcan and Helmer 1993). These methods consequently hold special pertinence to medicolegal cases, and they take two forms: craniofacial superimposition and facial approximation (see the section "Definition" and Fig. 1). Unlike its counterpart method, facial approximation is also routinely used for paleoanthropological (Balter 2009) and archaeological purposes (Prag and Neave 1997).

Craniofacial superimposition typically enables the determination of persons to whom the skull *does not* belong via image comparison, i.e., exclusion of individuals whose facial anatomy is inconsistent with that of the skull (Ubelaker 2002). Where multiple photographs and views of the face exist, and/or the teeth are visible, increased weight to positive matches may be assigned. On the other hand, facial approximation is used to predict the facial appearance from a skull (Gerasimov 1955). In medicolegal contexts, correct recognition of the publically advertised facial approximation is ideal; however, successes may also be attained via facial approximation's ability to capture public attention and focus it on the jointly advertised case details that, in turn, provide the stimulus for recognition (Stephan 2009). In non-forensic contexts, facial approximation may be employed to illustrate the potential facial appearance of the individuals to whom the recovered remains belong (Prag and Neave 1997; Balter 2009), and it is largely used in this context to boost public interest in archaeological finds. In these circumstances, facial approximations are typically constructed with greater detail and greater artistic license because the faces serve educational/entertainment purposes whose accuracy is impossible to verify (Montagu 1947).

Historically, superimposition and facial approximation coevolved from early attempts to authenticate the identities of skeletons thought to represent well-known historical figures (İşcan and Helmer 1993). The implementation of facial approximation methods predates, however, that of craniofacial superimposition (see Kollmann and Büchly 1898; Pearson and Morant 1934). In terms of medicolegal work, the first published use of facial approximation for homicide case investigation comes from the USA in 1916 (Wilder and Wenworth 1918) while that for craniofacial superimposition comes from Scotland in 1937 (Glaister and Brash 1937). While His (1895) is routinely

Facial Approximation and Craniofacial Superimposition, Fig. 1 Craniofacial superimposition and facial approximation: (**a**) semitransparent vertical skull wipe during video superimposition to compare the skull and face (the skull in this case belongs to the person depicted in the facial photograph); (**b**) a facial approximation that was constructed without a priori knowledge of the facial appearance of the correctly matching individual depicted in (**c**). (Parts (**b**) and (**c**) are reprinted from Stephan and Henneberg (2006), with permission from Elsevier)

cited in the scientific literature for first implementing facial approximation techniques, Sefner's attempt to construct Bach's face was not undertaken in the blind and so it does not qualify as face prediction (His 1895).

Of the two methods, craniofacial superimposition is widely recognized to be the more reliable, and should always be given precedence if a short list of potential candidates for a match, and antemortem photographs of the decedent, exist (Stephan 2009). Where this is not the case, facial approximation is warranted. Note here that facial approximation has been cautiously regarded in the broader anthropological realm due to its weak scientific foundations (Tyrrell et al. 1997; Stephan 2009). Even greater skepticism has been directed toward paleoanthropological approximations due to their larger degrees of subjectivity (Montagu 1947).

Typically, anthropologists or anatomists should be employed to execute the methods because of the method's anatomical underpinnings. However, where the anatomist/anthropologist does not possess the requisite knowledge/skills in photography (craniofacial superimposition) or dexterity for modeling (facial approximation), collaborations should be pursued with other relevant parties (photographers and artists) as appropriate.

Definition

Craniofacial superimposition (also known as photo superimposition, video superimposition, and supraprojection) is the simultaneous comparison of skull and face anatomy via the mixing of photographic or video images to determine their degree of correspondence (see Fig. 1).

Facial approximation (also known as facial reconstruction, facial reproduction, and forensic sculpture) is the prediction of a face from a skull without a priori knowledge of the decedent's true antemortem facial appearance (see Fig. 1).

Key Issues

Craniofacial Superimposition

Superimposition progressed from the overlay of tracings of the skull and face to the overlay of photographic still images and then to motion pictures in the 1970s (Taylor and Brown 1998). The latter method, which largely remains unchanged

Facial Approximation and Craniofacial Superimposition, Fig. 2 Some properties of rendering a 3D scene to a 2D photographic plane: (**a**) at short subject-to-camera distances, parts of objects closer to the lens are magnified; (**b**) an object's profile depends on the subject-to-camera distance used; and (**c**) spherical objects are broadened when they fall toward the edges of the camera's field of view. (Parts (**a**) and (**b**) are redrawn after Gavan et al. (1952))

up until the time of this writing, requires two video cameras: one to film the 3D skull and one to film the 2D facial photograph. The two acquired 2D images (one of the skulls and one of the photographs) are then mixed together and viewed on a single screen for the craniofacial alignment to be assessed.

It is crucial to understand that the raw anatomies of the skull and the face are not compared in craniofacial superimposition. Instead, it is the rendering of these 3D structures onto two 2D planes (i.e., their point projections) that form the platform for the comparison. Thus, the photography conditions used to capture the 2D images must be very nearly the same for a valid superimposition to be made.

Since specific settings have normally been used to acquire the preexisting 2D facial image, the task for the superimposition analyst is to recreate the photographic conditions for the skull recording (Taylor and Brown 1998). Modern video superimposition holds a major advantage above its older still-frame counterparts in this respect because the skull can be moved, with real-time superimposition viewing, for fast and correct placement relative to the face. Of course, the superimposition procedure is most accurate and expedient if the photographic conditions are known and can be set prior to skull alignment (e.g., Glaister and Brash 1937). This is best attained by asking the photographer, who took the original antemortem photograph, what photographic settings were used. If the photographer cannot be consulted, trial and error is usually pursued to approximate (as closely as possible) the photographic settings used for facial image capture (Taylor and Brown 1998). These photographic variables include the following:

- *Subject-to-Camera Distance*: The subject-to-camera distance must be replicated so that (1) parts on the 3D object closer (or further) from the camera are not differentially magnified between the comparison images (Fig. 2, or for real-life examples Fig. 3 – Panel 1), and (2) the camera does not record different edges of the same three-dimensional object (Fig. 2, or for real-life examples Fig. 3 – Panel 2). This is especially important when small subject-to-camera distances (<5 m) are employed.
- *Film Plane Relative to the Subject*: The angle of the film plane relative to the subject (i.e., camera tilt) must be replicated so that the degree to which the top or bottom of the subject vanishes (= keystone distortion) is the same. This factor also helps to determine the vertical height at which the camera is placed relative to the subject and vice versa.

Facial Approximation and Craniofacial Superimposition, Fig. 3 Changes in object appearance with photographic factors. **Panel 1** – change in object shape due to differential magnification as a result of subject-to-camera distance: (*1a*) a cube photographed with a Nikon D700 camera body fitted with a Nikon 60-mm 2.8 speed lens at a distance of 0.7 m; (*1b*) the same cube photographed with the same camera and lens, but with a camera-to-subject distance of 4.0 m (cube is rescaled for size); and (*1c*) superimposition of the two photographs, aligned on the cube's leading inferior corner. **Panel 2** – change in a spherical object profile due to change in subject-to-camera distance: (*2a*) skull shot with a Nikon D700 camera body fitted with a Nikon 60-mm 2.8 speed lens at 0.6 m; and (*2b*) the same skull photographed with the same camera and lens, but at a subject-to-camera distance of 3.0 m. Note: (i) the marked contribution of the frontal eminence and the occipital bun to the skull outline in *2a* but not *2b* (*white arrows* in *2a*); (ii) the left maxillary central incisor and the superior hinge for the calotte, which is visible in *2b* but not *2a* (*white arrows* in *2b*); and (iii) the more posterior placement of the zygomatic region in *2b* compared to *2a* (*grey arrow*). **Panel 3** – elongation of an object at the edge of the field of view, due to point projection onto a 2D plane: (*3a*) photograph of five identical spheres (*golf balls*) spread across the field of view of a Nikon D700 camera body

- *Position of the Subject in the Field of View*: The position of the skull in the field of view must reflect that of the face because the point projection of a 3D scene to a 2D plane results in the elongation of objects if they are located far from the center of the field of view (Fig. 2, or for real-life examples Fig. 3 – Panel 3).
- *Camera Equipment*: It is helpful to use the same or similar camera equipment for consistency of images (e.g., Glaister and Brash 1937). Note here that using different focal length lenses does not affect the perspective of the object at a given camera-to-subject distance, but does affect the zoom of the object and thus the resolution on the recorded image.

In terms of method accuracy, the most comprehensive study of craniofacial superimposition was undertaken by Austin-Smith and Maples (1994) who found a false-positive match rate of 9% when three skulls were compared to c. 100 facial photographs in either frontal or profile view. When both front and profile skull-face views were simultaneously used for comparison by these same authors, the false-positive rate was reduced to <1%.

Facial Approximation

Face prediction from the skull is a challenging task that requires a high degree of dexterity when the face is manually constructed (Gerasimov 1955). For this reason, anthropologists have often collaborated with artists and computer automated methods have been pursued to reduce the subjectivity of the methods (Tyrrell et al. 1997). While statistics and computer automation hold many advantages for standardizing methods, decreasing subjectivity, and increasing replicability (Tyrrell et al. 1997), obstacles remain and most of these methods have not been validated or made publicly available. As a result, manual facial approximation methods (clay-based sculpting and/or drawing) continue to be popular.

A replica of the skull is often used as a scaffold for facial approximation so that the original is spared of any damage and can be used as a reference during the face construction process (Fig. 4). Mean soft tissue depths are normally represented on the replica skull to indicate the amount of soft tissue typically overlaying the skull (Figs. 4 and 5). Methods for face construction vary according to the degree of weight that an analyst chooses to award to mean facial soft tissue depths or individualized face anatomy (Prag and Neave 1997). It is common for the temporalis and masseter muscles to be constructed (Fig. 4), or at least considered, in the face construction process according to the rugosity of their bony attachments. The muscles of facial expression may also be added (Prag and Neave 1997), but their construction according to stereotypical anatomical patterns should not be mistaken for scientific derivation of individualized face anatomy. A multitude of soft tissue prediction guidelines exists for face modeling (Gerasimov 1955); however, many have not been empirically derived or tested, and those that have been subject to validation tests do not often stand up to scrutiny. Space does not permit for a complete listing of these soft tissue prediction guidelines; however, some that have been recently analyzed and verified include:

Setting the:

- Eyeballs so that the corneal apex is c.16 mm anterior to the lateral orbital wall and its edges are closer to the orbital roof and lateral orbital wall
- Inner corner of the eye fissure c. 5 mm lateral to the medial orbital wall, and the lateral corner of the eye c.4.5 mm medial to the lateral orbital wall
- Level of the eye fissure c.10 mm below the frontozygomatic suture or at the level of the malar tubercle
- Nose width to 167% of the nasal aperture width

Facial Approximation and Craniofacial Superimposition, Fig. 3 (continued) fitted with a Nikon 60-mm 2.8 speed lens at a distance of 2.1 m; (*3b*) close up view of the center ball (III) and the left most lateral ball (I; note the elliptical shape of I in contrast to III); and (*3c*) superimposition of the center ball and the left most lateral ball, aligned at their left margin, to illustrate differences (Thanks go to T. Nguyen for photography support)

Facial Approximation and Craniofacial Superimposition, Fig. 4 Time-lapse sequence of the facial approximation of Renpit-Nefert (one of the Egyptian Mummies at the South Australian Museum, Australia): (**a**) laser-sintered skull from CT data; (**b**) laser-sintered skull with voids and undercuts filled using dental-modeling wax); (**c**) plaster skull cast with mean soft tissue depth markers in place; (**d**) skull with eyes and facial muscles added; (**d**) partially completed facial approximation (dowels track the location of the external auditory meatus); (**f**) addition of clay sheets to simulate the skin and subcutaneous structures; (**g**) the facial approximation after refinement of the nose, smoothing of the skin surface, and addition of lips and ears; and (**h**) completed facial approximation

- Height of nose wing to the height of the crista conchalis on each side
- Mouth width to 133% of the distance between the lateral most aspects of the canines
- Heights of the lips to approximate the height of the enamel of the font teeth
- Lip closure line to one third of the way up the central incisors
- Bony meatus of the ear c.5 mm anterior and inferior to the soft tissue meatus of the ear

In medicolegal contexts, atypical skull anatomy should be represented in the facial approximation wherever possible since it may trigger recognition. This includes atypical dental features, which may mandate the face to be set with an open smile. For casework, the completed facial approximation should be photographed in black and white so as to play down color that cannot be predicted from the skull (e.g., eye color). Advertisements of the facial approximation should be made on a "slow media day" when other major news events do not detract from the facial approximation advertisement. Additionally, the analyst should retain control over what images of the face are released so as to maximize opportunities for recognition success. In archaeological and paleoanthropological contexts, the faces are typically given full expressions, decorated and dressed consistent with the time period, and are photographed and/or displayed in full color (see, e.g., Prag and Neave 1997; Balter 2009).

The accuracy of archaeological and paleoanthropological facial approximations is difficult, if not impossible, to assess because antemortem facial records for these individuals rarely exist. In the historical context, comparison to artistic portraits holds severe limitations since these portraits represent the artist's rendered perception of the subject (Gerasimov 1955). Despite numerous small sampled studies in the medicolegal context, no consensus on the method's accuracy is held

Facial Approximation and Craniofacial Superimposition, Fig. 5 Mean soft tissue thicknesses, at craniometric landmarks, as collated from the literature for adults and subadults. (Illustrations and data reprinted from Stephan and Simpson (2008a, b), with permission from Blackwell-Wiley)

since there are as many papers reporting poor success as there are studies reporting high success (Stephan 2009). Note that casework success rates cannot be used as a measure of facial approximation's accuracy due to confounding factors (e.g., facial approximations are accompanied by written case details, and analysts define and record successes in different manners) and that in this applied field, greater motivation exists for analysts to report their successes than to publically disclose their failures. Recent research on the anatomical validity of the guidelines used for face prediction have found considerable errors and much of the research effort now focuses on the production of more accurate face prediction rules, including computer automated statistical methods for face prediction. In terms of replicability, there is unanimous agreement that facial approximation's is poor (Tyrrell et al. 1997; Stephan 2009). Despite these limitations, previous successful employment of the method in forensic casework justifies its future use.

Falabella, Fernanda

Victoria Castro
Universidad de Chile, Universidad Alberto Hurtado, Santiago, Chile

Basic Biographical Information

Fernanda Falabella is a South American archaeologist. She was born and grew up in Santiago de Chile. After high school, she attended a course given by a university professor to a group of volunteers in archaeology who were doing fieldwork along the coast near Santiago, and recognized immediately a passion for the questions being asked and the potentials of the answers being explored. She enrolled in the Licenciatura of Anthropology program at the Universidad de Chile, studying archaeology. She obtained the title of archaeologist in 1979. Her thesis focused on pre-Hispanic horticultural societies in Central Chile starting a long-term research of cultural processes in this region. She has conducted research on various topics related to the cultural practices and the social organization of these groups, such as dietary patterns, ceramic technology, resources circulation, settlement patterns, and identities. Parallel to these academic and scientific activities, she got married and raised three children.

Currently, she is a professor at the Universidad de Chile, where she has been a faculty member of the Department of Anthropology since 1977, involved in the formation of many generations of archaeologists in Chile. In the last years, she has given mainly courses in methods and theory of ceramic analysis and courses in technology and style in archaeology.

She was member of the board of directors of the Chilean Society of Archaeology for 15 years, being its president from 1991 to 1997, and has actively participated, until present, in various editorial, academic, and governmental agencies scientific committees dealing with the field of Archaeology.

Major Accomplishments

Fernanda Falabella's career in archaeology, spanning four decades, has been focused in understanding pre-Hispanic societies in Central Chile. Her pioneering research in the coastal area, near the banks of the Maipo River, resulted in a new local cultural sequence and introduced a new explanation for the social developments that superseded up to then accepted traditional diffusionist theories. In collaboration with archaeologist M. Teresa Planella, they identified the different cultural contexts in the area, describing their contexts and introducing new interpretations. Their studies on Llolleo and Bato cultural units brought about a new approach that emphasized diversity. During the decade of 1980 she did research in line growth and in oxygen isotope analyses in mollusks in collaboration with other researchers, and with the support of FONDECYT (a program of the Chilean Science Foundation). In the 1990 she was involved in studies of ichthyo-archaeology that concluded in the publication of an ichthyo-osteoarchaeology of fishes from Central Chile.

In the last 15 years, she has conducted and participated in several research projects supported by FONDECYT on the same horticultural groups of Central Chile in the inland valleys, searching to understand cultural patterns, mobility, interaction networks, and exploring how these societies configured their social relations at different spatial and social scales. Basic to these questions were the settlement pattern data, a product of projects conducted in the basins of Santiago, Rancagua, and along the Maipo River in collaboration with archaeologists Lorena Sanhueza and Luis Cornejo. Her research on stable isotopes in pre-Hispanic populations from Central Chile contributed to the understanding of maize introduction and how its dietary importance changed through time in this area; provided information on the contribution of marine resources, as food, in coastal groups; and offered new insights on mobility patterns. In the last years, she has been conducting research focused on studying social relations at the local level, with an emphasis on communities of practice.

Fernanda Falabella has a special dedication to ceramic studies. She received a grant in the 1990 for a comparative investigation on mechanical and morphological properties of pottery from the Early, Intermediate, and Late Ceramic periods, and she has participated in several national and international collaborative projects to study clay sources and the provenience of ceramics from archaeological sites.

Farming-Language Dispersals (1): Principles

Paul Heggarty[1] and David Beresford-Jones[2]
[1]Department of Linguistic and Cultural Evolution, Max Planck Institute for the Science of Human History, Jena, Germany
[2]McDonald Institute for Archaeological Research, University of Cambridge, Cambridge, UK

Introduction and Definition

Among various potential "windows on our past," one rich seam of data is all too often overlooked: the linguistic record. Above all, much of the world is so dominated by just a handful of vast language lineages as to cry out for explanation. That explanation, moreover, can only lie in the same contexts and processes that shaped humanity's cultural and population (pre)history more widely. Indeed, of all attempts to account for these broadest of patterns in the linguistic panorama, one of the most ambitious generalizations is the "farming-language dispersals hypothesis." Most simply put, this proposes that many of the most significant language families – in both geographical range and speaker numbers – dispersed along with, and primarily thanks to, the spread of agriculture. If so, then the modern panorama of linguistic relationships and diversity across the world would in effect still reflect, at least on the very broadest scale, the impact of the "Neolithic Revolution."

The basic mechanism invoked by the farming-language hypothesis is population growth and expansion. This is clearest where developed, sedentary farming comes to be contiguous with mobile hunting and gathering. For in favorable environments, at least, agriculture can support far greater population densities; the farmer population, then, is assumed to grow and spread geographically at the expense of the forager one. This outcome is then taken to be mirrored in the fates of the respective languages they speak. As the agriculturalists disperse, they take with them their language, and as it spreads it naturally diverges, ultimately into a broad family of related languages. The hunter-gatherers' languages, meanwhile, if they survive at all, end up cantoned into inhospitable areas of little value to agriculturalists.

As one instance, such has been the fate of most of the languages once spoken across southern Africa. Just a handful of languages of the foraging San and pastoralist Khoi peoples have survived here, and ever more perilously now, against the tide of the Bantu family (e.g., Zulu and Xhosa) arriving with incoming farming populations originally from further north. This conspicuously one-sided outcome is duly invoked as a paradigm case of the farming-language dispersal hypothesis. Many scenarios worldwide are much less straightforward, of course, although much of the debate has nonetheless unhelpfully polarized around all-or-nothing stances either for or against the hypothesis, as if it were valid for almost all major language dispersals, or none.

Here, we are at pains to avoid any such all-or-nothing visions, hence the qualifications already built into the working definition just given: *many of the most significant language families*. That is, this formulation refers to the dispersals of language *families*, not just single languages, and makes no claim to explain *all* language families, particularly not the more minor ones. Moreover, this working definition is in any case taken only as a useful starting point from which to explore a range of refinements and challenges to the hypothesis (hence also various alternative formulations of it, by both advocates and critics). Much hangs in particular on just *how many* language dispersals are attributed to farming, and *how uniquely*, given that languages can clearly also be spread by many other factors.

Historical Background

Among the first to set out the hypothesis was Renfrew (1987), who applied it to the one language family that has long accounted for the native tongues of a far larger share of the world's population and land area than any other: Indo-European. Renfrew assumed a genetic signal too, for his model calls directly upon Ammerman and Cavalli-Sforza's (1984) vision of farming spreading by "demic diffusion" in a "wave of advance."

From the start, controversy has surrounded the hypothesis. For Indo-European, it directly challenged traditional thinking among specialists in the family's language prehistory and among those archaeologists who had built such linguistic interpretations into how they read the material culture record too (e.g., Mallory 1989). Undaunted, Renfrew (1989, 1991) soon sought to generalize the hypothesis, stoking a debate embodied particularly in the many contributions to Bellwood and Renfrew (2002), ranging across much of the world. Diamond and Bellwood (2003) and Bellwood (2005: ch. 10), moreover, specifically explore how the hypothesis might apply on a worldwide scale. The attendant controversy, meanwhile, is neatly summed up by Golla et al.'s (2003) riposte that the hypothesis "more frequently distorts than illuminates the histories of the speakers of the world's languages." For a more extensive skeptical response from linguists, see also Campbell and Poser (2008: 337–50).

Both as a general principle, then, and in a host of individual cases worldwide, it remains hotly disputed whether the farming-language dispersal equation is a valid, fundamental insight into human prehistory or a simplistic and unproven generalization. One can be forgiven for coming away from the debate in the literature with the impression of a sterile standoff between those who would overegg the role of agriculture and those who would unduly minimize it. (As an example, see some of the commentaries published with Heggarty and Beresford-Jones 2010).

For its part, this contribution seeks above all to clear a path through the traditional all-or-nothing stances – or at least the mutual accusations painted

in such stark terms. It explores the general issues of principle that attend the hypothesis, illustrated from among the ongoing debates on the various claims to apply it to many a language family around the globe. A fuller and more systematic worldwide survey, continent by continent, is provided in the next entry in this encyclopedia, ► "Farming-Language Dispersals (2): Worldwide Survey."

Key Issues/Current Debates

The hypothesis can certainly benefit from important qualifications and refinements on a number of levels. Once these are borne in mind, though, many objections and apparent counterexamples lose their edge, and much of the controversy is defused. This entry will now summarize in turn each of these key limitations and refinements to the hypothesis. For a fuller treatment, see Heggarty and Beresford-Jones (2010).

All, Some, or Which Language Families?

The first essential qualifications are those already built into the working definition of the hypothesis as followed here: *many* of the world's *most significant* language families.

Firstly, most obviously and most crucially, *many* does not mean *all*. Even the most ardent advocates of the hypothesis explicitly acknowledge (e.g., Bellwood 2005: 2) a good number of language families to which it patently does not – indeed cannot – apply, and which were evidently spread by *non*-agricultural societies, as we shall shortly see. There *can be* no claim to universal and unique validity, then. That said, in the eyes of some critics, many proponents of the hypothesis do nonetheless err in that direction: imputing far too exclusively to farming many a language dispersal that evidently relied heavily on other factors.

The second qualification – the most significant language families – is usually tacit. The hypothesis was first conceived especially for a number of the most widespread and populous language families, dispersed long before the modern era, and indeed thus proposed to date back to the "Neolithic Revolution." Some criterion of scale, both in chronology and internal diversity, is inherent in the specification *families* (rather than single languages), but that too is often not clarified. Here, both qualifications are made explicit, particularly since criticism is often strongest and most telling when the hypothesis is "pushed" to apply even to very recent dispersals of single languages, especially out of Europe during the ages of colonialism and imperialism.

All or Nothing? Importance Relative to Other Factors

For a language replacement to happen, some factor(s) must be decisive enough to confer upon one human group – or at least upon its language, usually as part of a broader cultural complex – some greater impulse, ability, or propensity to expand, at the expense of others. Or to see this from another perspective, a language dispersal may in principle be driven by *any* process able to confer such greater expansive propensity.

There are of course many plausible candidate demographic and sociocultural processes with the potential to precipitate language expansions. The "coming of agriculture" is just one of the possible players, then. In principle, any given language dispersal might be attributable to any one such process or any *combination* of them. So the real question is just how significant farming was vis-à-vis other processes in any given case.

It is only the polarization of the debate that deforms this into a false all-or-nothing question. Take the settlement of Micronesia and Polynesia. For Diamond and Bellwood (2003: 598), this is one of their "two clearest examples" of a farming-language dispersal. Golla et al. (2003), meanwhile, retort that it "was driven by the development of sophisticated seafaring technology, not farming success." Note that neither party disputes the linguistics – an expansion of the corresponding subbranch(es) of the Austronesian language family – nor the chronology, nor even that the settlers were both farmers and great seafarers. They in fact disagree only on which of those two attributes essentially accounts for the expansion.

Yet there is no justification in any case for framing the question in exclusive terms either way ("by seafaring . . . not farming"). More to

the point is what was the *respective* significance of one factor as opposed to the other(s). This entails also thinking in terms of sufficient conditions and limiting factors. In this case, it seems obvious that neither farming nor seafaring technology alone was a *sufficient* condition. Without farming, the populations that settled the remote Pacific islands could not have flourished as they did. But equally, they could not have reached those islands in the first place without great seafaring skills.

Nonetheless, the *limiting* condition was not agriculture. Many other populations in the wider surrounding region (East and South Asia and the Pacific Rim) were farmers, without this having enabled them to colonize Micronesia and Polynesia. That could be achieved only by those who developed the necessary seafaring prowess. Only that can complete the explanation of why the region's languages are of *Austronesian* lineage, rather than stemming from one or more of the many other language lineages spoken by other "surrounding" agriculturalist populations. In any case, the particular ("Oceanic") subbranch of Austronesian spread across the furthest-flung islands of the Pacific is hardly a paradigm instance of the hypothesis as Diamond and Bellwood (2003: 598) themselves define it. For in all of Remote Oceania, this was no "replacement of local hunter-gatherers by expanding farmers" but a first settlement – another reminder of the range of contexts to be borne in mind.

Simply to *identify* the speakers of a language lineage as farmers, then, is by no means to demonstrate that it was *because* of farming that they and/or their language lineage were able to expand. Similarly, simply desiring or needing land for farming is no explanation, since that alone does not entail enjoying the wherewithal actually to take it, at the expense of others. As explored below and in the entry on ▶ "Farming-Language Dispersals (2): Worldwide Survey" in this encyclopedia, alternative and additional factors were evidently also at play in many language family expansions worldwide. Even the classic instance of the Bantu dispersal proceeded *pari passu* not just with farming but with ironworking too.

The farming-language dispersal hypothesis has come in for particular criticism when applied to the spread of European languages across the globe during the periods of colonialism and imperialism. Again, it is certainly not agriculture that can explain *which* particular languages spread (and which did not), across which regions, and at which times. Why was it specifically English, Spanish and Portuguese that became the languages spoken by most people in the Americas today, for example, rather than French, German, or indeed Hindi or Chinese, also spoken by farmers? What does explain this straightforwardly, of course, is a combination of well-known demographic, social, political, cultural, and technological factors and indeed historical happenstances. Whatever ultimate causation those factors might themselves eventually be traced back to on the grandest scale, as a practical, direct explanation for the dispersal of any *particular* language lineage, one must in the first instance invoke any evident proximate factors and historical contingencies. To see language expansions of the modern era, in particular, as driven *primarily* by agriculture rather than by a host of other relevant factors, is greatly to overstate the case.

Farming as a Special Case?

Since so many factors may in principle be involved in spreading a language family (for a survey see Heggarty 2014; Heggarty and Renfrew 2014), the real judgment of the value of the farming-language dispersal hypothesis hangs on whether the advent of farming was just one contributing factor among many equals, or whether there is anything special about it as unusually powerful vis-à-vis most others.

The tendency to overegg how widely the hypothesis applies, especially in recent historical cases, is unfortunate and does a disservice to what is nonetheless a significant insight. For the general principle does still stand: it is expansive processes in the real world that shape the dispersals of our language lineages. Given this cause-and-effect relationship, it would be curious if such a defining, cardinal change in the trajectory of human societies as the transition to agriculture had somehow left precious little imprint in the fates of the language lineages that those societies spoke. On

the contrary, it is only to be expected that the Neolithic should have impacted upon the human linguistic panorama too.

Again, then, the question is most sensibly seen as a matter of degree: Just how significant a role may the spread of farming have played in how many of the world's major language expansions?

Genes and Language

On another level too – that of human genetics – things are often far less straightforward than in the paradigm instance of the hypothesis, which pits hunter-gatherers against a demographic "wave of advance" of faster-growing and much denser farming populations.

For language expansions may come about by either of two very different mechanisms (or indeed by any complex of both). On the one hand, a speaker population itself may expand territorially, taking its language with it into ever more extensive territories, largely ousting any population there previously and their language(s). Linguistic lineages thus remain in step with genetic ones. On the other hand, speakers may largely stay put, but switch to speaking another language – usually one to which some distinct (social) utility attaches, thanks to its association with some prestigious cultural complex that is doing the expanding in this case (rather than an actual population). The outcome this time is that linguistic and genetic lineages no longer match.

It makes a great deal of difference, then, whether the language spoken in a given territory changed either because the people who spoke it were themselves largely swamped by incomers (as in much of North America in the last few centuries) or because significant native populations remained, but switched to an outside language (as continues today in parts of Mesoamerica and the Andes).

The demographic logic at the core of the farming-language dispersal hypothesis entails essentially the former: farmers spread largely by outpopulating the hunter-gatherers, so there should be a human genetic expansion in step with the linguistic one. There is little doubt that in appropriate environments agriculture can support population densities an order of magnitude greater than hunting and gathering can. Yet in several cases where a given language family is argued to have dispersed in tandem with agriculture out of the same "homeland," the genetic lineage of many of its speakers in fact points elsewhere. Almost all of Island Southeast Asia, for example, is dominated by languages of the Austronesian family that hail ultimately from (pre-Han) Taiwan; whether their speakers' genes majoritarily do, however, is more contentious (see, e.g., Donohue and Denham 2010).

Yet one must be clear on exactly what the "wave of advance" model predicts in any case, which is not the *entire* replacement of hunter-gatherer populations by expanding farmers. On the contrary, it accommodates both interbreeding and some adoption of farming by hunter-gatherers on the advancing farming "frontier," and thus actually predicts that the proportion of "farmer" to "hunter-gatherer" genes should progressively decrease with distance from the agricultural homeland. In the case of the Indo-European-speaking populations of Europe, some early studies (e.g., Balaresque et al. 2010 on paternal lineages) do indeed reveal genetic clines away from the family's putative "farming homeland" in Anatolia – although there is no lack of counterclaims too. Further complexities are that the Y-chromosome and mtDNA genetic lines often give quite different results, indicative of different histories for male and female populations, respectively (see, e.g., Forster and Renfrew 2011), while autosomal results can be different again.

The advent of both full-genome and ancient DNA analyses is now revolutionizing the field in any case. Earlier genetic results are rapidly being superseded with far greater resolution and fast-improving coverage over geographical space and through time. Ancient DNA brings obvious potential to advance the unsettled debates on farming/language dispersals as hypothesized for many an individual language family, and in some cases may in time help settle the issue. Major findings already bear very directly on the case of Indo-European, for instance (see under "Farming-Language Dispersals (2): A Worldwide Survey"). More generally, ancient DNA has already shown its power to bring big surprises that call for

significant rethinking of the contexts in which farming arose and spread in any case. Early farming populations from three different parts of the Fertile Crescent have turned out unexpectedly distinct from each other genetically, taken to attest to population splits dated back tens of millennia (Lazaridis et al. 2016). In fact, the strongest claims for farming/language dispersals have long proposed that not just one language family spread with farming out of the Fertile Crescent, but three: Bellwood (2005) argues for Indo-European, Afro-Asiatic, and even a hypothetical "Elamo-Dravidian." Orthodox linguistic classifications do not accept that the last of those ever actually existed, however, and the ancient DNA data by no means clearly support Indo-European as the language lineage that dispersed with farming out of central/eastern Anatolia. In short, ancient DNA is fast bringing plenty new fuel and new thinking to the debate on the farming-language dispersal hypothesis, but overall, for now, the geneticist jury is still out.

Hunter-Gatherer Language Expansions

And what of those major, expansive language families first spread and still spoken by populations not of farmers but of hunter-gatherers? Prime examples are three families of North America, particularly the far north, namely, Eskimo-Aleut, Algic (mostly Algonquian), and "Na-Dene" (alias Athabaskan-Eyak-Tlingit). These three, along with Pama-Nyungan in Australia (at least on the standard view that it is a true family), are repeatedly cited by critics who interpret them as disqualifying the hypothesis: language dispersals, but without farming.

Yet that is again entirely to misconstrue the claim, as if farming can or even must account for *all* language expansions. It obviously does not and cannot, as is nowhere clearer than in the particular parts of the world where these major "hunter-gatherer language families" are (or at least were) spoken. For large parts of their territories are Arctic, subarctic, or arid regions where farming is essentially not viable at all, or only marginally so. Whatever happened here can hardly undermine a hypothesis about the impact of farming, which by definition is simply not applicable in those regions. To be crystal clear, then, one might even preface the definition of the hypothesis with a further explicit qualification, namely, that "*across those parts of the world where agriculture became established before the Modern Era*, many of the most significant language families – in both geographical range and speaker numbers – dispersed along with, and primarily thanks to, the spread of agriculture *there*." Strictly, of course, such a qualification is redundant, because "the spread of agriculture" by definition limits the claim to only those regions and periods through which farming could and did indeed spread. Nonetheless, since this issue has generated so much misunderstanding and polarization, it is still valuable to spell out the qualification explicitly.

It is clear to all sides in the debate, then, that hunter-gatherer language expansions unquestionably have taken place. The hypothesis hardly denies that; on the contrary, it is best understood from precisely this perspective. For what it actually claims is effectively just this: *only* (by definition) in those regions of the world where original hunting and gathering has since been *replaced* by farming, that very process of agricultural expansion may offer a plausible account for a number of major language family expansions also visible across such regions.

In this perspective, the relevance of known hunter-gatherer language dispersals is simply as evidence of the obvious: that there are certainly other factors besides farming that can lead to language expansions and, more specifically, that those factors may even include the other basic mode of subsistence that farming itself has since so often replaced. These most widespread of all hunter-gatherer language families are thus in fact perfectly consistent with the even more general framework to which the farming-language hypothesis belongs: the subsistence/demography model (for discussion, see Heggarty and Renfrew 2014: 39–40). On that broader logic, all that matters is that a given set of subsistence technologies – whether for hunting, farming, pastoralism, or any other subsistence regime – confers on the population that uses it, and/or on their cultural package (language included), markedly greater expansive

potential over other populations/languages in a given region.

Differences in subsistence technology can be just as acute between two groups who both practice hunting and gathering – as per the scenario in which the Eskimo-Aleut language family, for instance, spread to replace the preceding "Dorset culture" and whatever language(s) they spoke. Indeed, in Greenland the Inuits' successful hunter-gatherer subsistence contrasts just as starkly with the ill-fated Norse *farming* settlements, in the face of a changing climate. Such cases are far removed from the prototypical instance of the hypothesis, and they fail to meet the obvious precondition that the environments must be amenable to farming in the first place.

It may be no coincidence, then, that the most striking expansions of hunter-gatherer language families played out in large part across extreme, marginal environments such as the Arctic, subarctic, or the arid interior of Australia. It is precisely where conditions are so harsh that the net gain conferred by specific innovations in subsistence technologies can be all the greater and more exclusive, as in the case of the Inuits. In less inhospitable regions, meanwhile, hunter-gatherer language lineages (where they survive at all) more often present smaller-scale, more fragmented, and less exclusive distributions. (See the coverage of Amazonia under ▶ "Farming-Language Dispersals (2): Worldwide Survey.")

Farming Versus Foraging or Farming and Foraging?

In other respects too, many contexts are by no means so clear-cut as in the prototypical vision of the hypothesis. So it can hardly be expected to apply straightforwardly across all such contexts.

In practice, few subsistence regimes fall neatly into exclusive categories of either sedentary farming or mobile hunting and gathering. How much a population lives off food they produce rather than procure is no all-or-nothing contrast but a sliding scale. Along Peru's north-central Pacific coast, for instance, complex societies arose in the third millennium BCE based initially upon gathered maritime resources (uniquely rich here) more than upon farming. Is a language dispersal to be expected in such an intermediate case? It turns out that there is no evidence for any at this time depth here. In northern Europe, too, can we expect a straightforward farming-language dispersal, when coastal hunting and gathering (notably fishing) remained a rich subsistence resource long after the Mesolithic? On many scales, the "Neolithic Revolution" is of course better seen as a gradual *transition* between subsistence regimes (for many examples, see Barker 2006).

Different Forms of Farming

Agriculture itself, moreover, comes in a range of very different forms, which have by no means always been equal worldwide. In much of Amazonia, farming takes the form of slash-and-burn, shifting territory frequently along the region's great watercourses. Might this help explain the wide but unusually scattered distributions of language families there?

Meanwhile, and as in many parts of the world, farming in Island Southeast Asia is widely seen not as stemming from just one single and exclusive origin point but as having come together as a package of crops and livestock from various geographical sources (see Donohue and Denham 2010). So even in this case, where the claim for a farming-language dispersal is relatively strong and broadly accepted, it might enjoy greater consensus by conceding that it does nonetheless need to be qualified: the key components in the archaeological package were not *all* brought out of Taiwan by Austronesian speakers. Indeed, quite what proportion of them was, and just how critical they were, remains in debate.

In fact, many languages expand in encounters between two populations that *both* practice agriculture, albeit in different forms. In principle the basic hypothesis might make no prediction in such cases. Yet enthusiasts have nonetheless interpreted such encounters as farming-language dispersals, attributed now just to qualitative differences between the different forms of farming, one of them taken to confer some "superiority" in subsistence/demography terms. That vision would have the spread of European languages across the Americas, for instance, as reflecting some putative superiority of the Old World's

agricultural package over that of the New World. Yet that interpretation is in itself highly debatable, at least for crops if not livestock. Europe today lives on potatoes, maize, beans, and tomatoes, for example, just as much as the Americas live off European crops. The New World hearths of agriculture in Mesoamerica and the Central Andes are also precisely where indigenous languages have bucked the trend and *resisted* European ones in greatest numbers. And in any case, as already observed above, a host of other historical factors were in play in shaping Europe's impact on the Americas, in language as in so much besides.

Intensification Thresholds

That all farming is not equal also applies on the time dimension, of course, entailing another key consideration. Even within the same region, agriculture can have a significant impact on demography (and indeed culture), and with it possibly also on language, at more than one stage in time. Step-changes in technology and productivity (thanks to the development and spread of new crop strains or animal breeds, for instance) can take even established farming across successive "intensification thresholds." These may help account for certain language family trees that are disproportionately dominated by individual subbranches, which underwent later great dispersals of their own. Might this explain, for instance, the successive expansions of Sino-Tibetan and then of its main Sinitic subbranch; or of the Niger-Congo family and then its most famous subbranch, Bantu?

Sherratt and Sherratt (1988) even suggest that the Indo-European family might be the result not of the initial "Neolithic Revolution" at all, but of a following revolution a few millennia later, in "secondary products" such as wool and milk. This attempts also to bridge the chronological gap to the time depth traditionally assumed for Proto-Indo-European, three millennia or so after the Neolithic began here. Intensification thresholds have been invoked especially where farming (of some form) began before the first major language dispersals detectable in a given territory. One example would be the Japonic family (Bellwood 2005: 114); others include both the main families of the Andes, where it was not until relatively late that some large animals (camelids) were domesticated and a true cereal crop (maize) became ubiquitous (Heggarty and Beresford-Jones 2010).

Intensification thresholds might also be crossed thanks to critical new technologies or human transformations of the landscape on grand scales: terracing in Southeast Asia or the Andean highlands, for example, or great canals for irrigation and water control in Mesopotamia, China, or on the arid coast of Peru. These transformed agricultural productivity and thus population sizes, again with potential for concomitant linguistic impacts. This only serves to recall, though, that farming *per se* is not a full explanation, for it may in itself be shaped by other factors and in turn fed back positively into them. Only once complex societies grew to sufficient scale and levels of organization could huge labor forces be directed to vast public works for agricultural ends.

Language Dispersals Through Time

On each of the levels just explored, then, the farming-language hypothesis is subject to a series of qualifications, and agriculture competes with a range of alternative processes that can equally well underlie language dispersals. Among these many candidate "driving forces," though, can one still make some useful distinctions and generalizations?

One crucial perspective is the time dimension, and specifically the trajectory of the development of human societies. For the various expansive processes impacting on human populations have hardly kept the same significance relative to each other over the fluctuating course of prehistory. The fates of our language lineages are determined by causes that lie in the nature of human societies, but those societies themselves have been anything but constant through (pre)history. On the contrary, most have changed radically on a number of defining levels: in their ways of subsistence, in mobility or sedentism, in the scale and complexity of societal units, and so on.

Among key shapers of the *recent* linguistic past (as well as the present and immediate future) are

the rise of the nation state – and with it mass education, literacy, and language "standardization" – as well as long-distance mass transport and telecommunications. It is particularly because these phenomena are so far removed from any farming-language logic that critics have duly decried the hypothesis when invoked for relatively *recent* language dispersals that were clearly shaped by these much more immediate forces and by historical contingency. On the other hand, many of these forces so powerful today were simply absent for most of history, let alone prehistory. Before them, great complex societies nonetheless also drove spectacular language dispersals, not least the Romance (i.e., "Neo-Latin") family spread by Rome, or the more complex linguistic legacy of the Incas (see Heggarty 2008).

Rolling back further millennia still, the story is one of many individual "ups and downs" and societal collapses, but the long-term trend, at least, remains clear: human societies tended overall to be of lesser demographic scale and complexity. Also less acute, then, was the scope for disparities between societies in political and social organization, economic and military technologies, and so on. Ever fewer processes were yet in play that might so sharpen the disparities between human groups as to propel just a privileged few of them – and their languages – to expand dramatically at the expense of their neighbors. Except, that is, for the contrasts in subsistence regimes, and thus also in demography, that emerged in particular with the dawn of the Neolithic. Certainly, the advent of agriculture remains the single most significant transformation of human society and ecology, upon which so many subsequent transformations rest. It seems only logical that its linguistic impact too should have weighed heavy.

Indeed, to respect a principle of commensurate scale in cause and effect, the most potent linguistic impacts we see – that is, the most spectacular language family expansions, in territorial and above all demographic terms – demand explanation in terms of correspondingly powerful processes affecting the fates of human societies. Agriculture does stand out, then, as a uniquely plausible candidate for language expansions at this scale and at this early stage in the trajectory of human societies.

In chronology too, many of the deepest language families that we can detect appear to go back to timescales very roughly consistent with the "Neolithic Revolution" in their respective parts of the world. Such claims hold, though, only to the limited extent that one can trust in the controversial and inexact enterprise of "linguistic dating" at all, for it is necessarily attended by many grave caveats. In part this reflects how quickly languages naturally change, which also obscures their own origins and ensures that our ability to reconstruct language relationships back into the past ultimately fades and fails completely, at a ceiling usually estimated as of the order of ten millennia or so ago.

The great language expansions that we *can* detect, though, are also a function of those that ever took place at all. That we cannot reliably uncover any episodes of language (family) dispersal back before the Neolithic may not be coincidental, given the limitations on the nature and scale of human societies before then. For those limitations arguably entailed that it was less likely that any one group could enjoy some exclusive propensity to expand much more than others. For as far back as we can tell, the count of language *lineages* across the world appears to have progressively declined over recent millennia and at an ever-accelerating rate. Projecting back, at the dawn of the Neolithic, the picture may well have been one of a great diversity of language lineages, arisen over the tens of millennia since the first human settlement of most continents. (This necessarily refers to "effective diversity," i.e., of lineages independent at least as far back as language relationships can be identified. All lineages may in principle ultimately go back to a monogenesis of human language before *Homo sapiens* spread across the globe, but linguistic data certainly cannot aspire to reconstruct remotely so far back.)

Such a vision would fit with the general ethos of the farming-language dispersal hypothesis, but meets with objections in its turn. Hunter-gatherer language dispersals unquestionably have occurred, as we have seen. Nonetheless, the classic examples are largely limited to relatively

recent millennia and to extreme environments (to which hunter-gatherers have been restricted precisely by the demographic expansion of agriculturalists). On both grounds, such cases do not by any means necessarily offer robust analogies for hunter-gatherer groups in pre-Neolithic times and in more productive landscapes and temperate climes.

Another rider is the claim for putative "macro-families" of languages, such as those dubbed "Nostratic" or "Eurasiatic," that would go back to earlier dispersals still. These are rejected as but "faces in the fire" by linguistic orthodoxy, which disqualifies the methodology the claims are founded upon. They have nonetheless been entertained by some enthusiasts for the farming-language hypothesis (e.g., Bellwood 2005: 217), even if this seems rather ironic. For if such putative macro-families existed, then they would have to go back to dispersals at least several millennia *before* those attributed to agriculture. So to account for them would require some other, *pre*-agricultural transformation, that is, some rival expansive process(es) that would only undermine the claim that farming was a uniquely significant and powerful driver at great time depths.

To recap, then, the generalization suggested here focuses on the cumulative nature of developments in technology and social organization over the millennia (and even more so across the 1492 watershed). Over time, contrasts between one human population and/or cultural package and another – even where both had farming – became increasingly acute, not least in their propensity to spread at others' expense. And as they did so, the earlier great significance of agriculture per se diminished in relative terms, along with any ability to explain and identify *which* language families expanded where and when. This raises obvious parallels with the traditional concept of a scale from ultimate to proximate causation. On how this might usefully be adapted specifically to language dispersals, and for further exploration of this possible generalization, see Heggarty and Beresford-Jones (2010: 165–9).

The generalization just proposed radically reins in the ambition of how much of language (pre)history the farming-language dispersal hypothesis might be pushed to explain. That has the virtue, though, of thereby sidestepping many of the most persuasive recent "counterexamples" and focusing the hypothesis where its logic has most to offer: on the very broadest and deepest language expansions that we can detect, commensurate in scale and broad chronology with the key threshold stages in the transition from hunting and gathering to full-blown intensive farming. Just how, when, and whether such stages came to pass varied enormously from one part of the globe to the next, however, according to local cultural trajectories and timescales. So as with any such generalization, quite how this one might apply will likewise depend heavily on context, on all the levels explored here. This is precisely the lesson that duly emerges from how the farming-language dispersal hypothesis has fared across the world – as surveyed in more detail under ▶ "Farming-Language Dispersals (2): Worldwide Survey."

Future Directions

As that survey duly reveals, across many cases worldwide, our understanding of human prehistory does in principle have much to gain from the farming-language dispersals debate and the extent to which the hypothesis fares well or ill from one case to the next. This holds from both perspectives: how much of a role agriculture may have played in shaping the broad panorama of human language relationships and diversity, and how those language data might in turn contribute to assessing the impact of farming vis-à-vis the many other processes that shaped our cultural and population prehistory.

Besides the obvious potential of ancient DNA prospects for progress lie first in crossing the fault lines between the different disciplines involved, along which much of the dispute has aligned. For notwithstanding all the caveats that attend the idea of the "Neolithic Revolution," among archaeologists there is wide recognition of the scale of the impact of agriculture and its defining role, through the many changes that it ultimately set in train for the nature of human societies and the disparities

between them. Among linguists, however, there seems little recognition of what this entails: at least in principle, good reason to expect commensurate impacts in the linguistic record too. Rather, it is often specialists in the language families in question who have objected most strongly to any association with agriculture, particularly in those cases where the language data have hitherto traditionally been interpreted as setting a given family's first dispersal into a real-world context in prehistory very different to that entailed by any association with the spread of farming (see, e.g., Campbell and Poser 2008: 337–50).

Yet much linguistic commentary still betrays a rather simplistic vision of "the coming of agriculture," insensitive to the various key issues and refinements covered here. Moreover, many historical linguists' counterarguments have failed to convince in their turn, for relying so heavily on their own traditional techniques for seeking to identify those real-world contexts – techniques that themselves face heavy criticism as unreliable and too open to subjective interpretation. All too often, similar or even the same language data are interpreted by different linguists as implying quite opposite conclusions. "Linguistic paleontology," in particular, is often invoked as if it "proved" that the speakers of a given family's ancestor language either must or must *not* have been farmers, or collectors of wild grains, or indeed nomadic pastoralists, as in the debates on Indo-European, Afro-Asiatic, Dravidian, and Uto-Aztecan (see ► "Farming-Language Dispersals (2): Worldwide Survey"). Too much faith also continues to be placed in the supposed linguistic dating technique of glottochronology, when it has already been widely discredited for decades. For a survey of all such techniques (and their weaknesses), see Heggarty and Renfrew (2014).

Meanwhile, novel quantitative and phylogenetic approaches to language data, inspired by analysis techniques drawn from the biological sciences, are opening up new perspectives on some major language family expansions, on both the chronological and geographical levels (e.g., Bouckaert et al. 2012 on Indo-European). Results have more often than not supported associations with farming dispersals, although the methods continue to face objections from many linguists who hold to established, more qualitative interpretations of language data.

Linguistics and archaeology aside, we can look forward also to the revolutionary new potential of ancient DNA. This obviously has great power to inform on and test a farming/language hypothesis founded on a logic that is above all demographic. Even ancient DNA analyses, though, have in some respects remained contingent on presumptions of existing hypotheses, and the modelling choices they may dictate.

So above all, the best prospects for future progress would seem to lie simply in a greater balance in the debate, pulling back from polarized, all-or-nothing interpretations on either side. On each of the levels explored here, the farming-language dispersal hypothesis requires significant refinements and qualifications. Those duly rein in any overambitious claims for quite how much of our linguistic origins it might really explain. Equally, though, they serve to reconfirm that behind the complexities there nonetheless lies a fundamental logic. If the coming of agriculture was such a defining step that molded so much else of human cultural and population prehistory, it would seem all the more curious if our languages had largely escaped its otherwise pervasive impacts.

F

Introduction

The farming/language dispersal hypothesis, most simply put, proposes that many of the world's most significant language families – in both geographical range and speaker numbers – dispersed along with, and primarily thanks to, the spread of agriculture. The entry on ▶ "Farming-Language Dispersals (1): Principles" in this encyclopedia explores the range of issues and qualifications that attend this general hypothesis, to clarify those cases in which one might in principle expect that it would or would not hold true. Much necessarily hangs on the particular "real-world" contexts – cultural, chronological, and geographical – through which each of the world's major language families dispersed. Given the great diversity in those variables in the human story worldwide, the hypothesis duly does not play out consistently from case to case, or in others simply does not apply at all. Such is what this contribution now aims to survey, across the globe.

The first main exposition of the hypothesis already explored possible instantiations on four different continents – see Renfrew (1987: Chapter 11). Especially in the early 2000s, however, attempts have been made to apply it more comprehensively still on a worldwide scale. What follows here can but briefly survey, compare, and contrast the main debates from continent to continent. As well as the specific references given below in each case, further key sources include the dozens of contributions collected in Bellwood and Renfrew (2002). Note also Bellwood (2005: esp. Chapter 10), who pushes the strongest

interpretation of the hypothesis worldwide, but remains very far from commanding broad support – especially among historical linguists, notably Campbell and Poser (2008: 337–350). Finally, claims for farming/language dispersals are repeatedly debated, and set within a much broader survey of the many other aspects of language prehistory, in the eight continent-by-continent chapters by Heggarty and Renfrew, within Renfrew and Bahn (2014).

Key Issues and Current Debates

See the sister entry to this one: ▶ Farming-Language Dispersals (1): Principles.

Eurasia

East Asia enjoys the status of one of the world's rare hearths of agriculture and "pristine" civilization, home to vast populations since far back in (pre)history. The general subsistence/demography model (see under ▶ "Farming-Language Dispersals (1): Principles") – and more specifically, farming/language dispersals – might thus seem an obvious candidate explanation for this region's major language expansions.

Across *Inner China* particularly, language expansions have indeed often been imputed to farming, spreading southward out of the core domestication region (of cereals *other* than rice) in the North China Plain, along the Yellow River and immediately to its south. The linguistic story, though, is actually of *more* than one major expansion, but all usually taken to have begun out of this same general homeland area. The spread of Mandarin specifically, out of its northern origins, dates largely to recent centuries and is still ongoing. This expansion has clearly been determined by historical and political factors that bear only the most indirect of relationships to the rise of farming many millennia ago – indeed the languages that Mandarin has been replacing were also those of developed farming populations.

Stepping further back in time, however, Mandarin and its many sister languages within the Chinese (or "Sinitic") family only arose in the first place thanks to an earlier and wider expansion of (Proto-)Chinese as a whole. This most plausibly began some three to four millennia ago, out of the heartland region where the Yellow River runs through the North China Plain. Earlier still, by another couple of millennia or so, must have been the dispersal even further afield of the putative "Sino-Tibetan" family, which alongside Sinitic would include the Tibeto-Burman languages (a standard hypothesis, even if it does not quite command unanimity among linguists of the region).

Of these three expansions, only Sino-Tibetan would make for a rough fit with the chronology of initial farming expansion. A good number of scholars (e.g., Janhunen 1996: 222) have duly proposed a linguistic homeland in the middle Yellow River region, identified with the Neolithic Yangshao culture in the fifth and fourth millennia BC. Even that, however, is but a default starting hypothesis, given how many uncertainties remain in linguistic prehistory here.

As for the later and specifically Sinitic expansion, to entertain some link with farming would entail looking to some step-change(s) in agricultural intensification and productivity (see under ▶ "Farming-Language Dispersals (1): Principles"), perhaps thanks in part to grand-scale public works such as the great canal network. This intensification might thus have propelled another wave of demographic (and linguistic) expansion. But if so, this scenario only reinforces how by this stage farming alone is hardly the proximate explanation: it was only the growing scale and political control of complex societies here that could direct the great labor forces required for such intensifications in the first place.

On a much smaller scale – arguably a function of inherent geographical constraints – the independent *Korean* and *Japanese* language lineages are also often associated with farming expansions/intensifications. That said, each today shows far less internal diversity than would be expected to have arisen since the initial spreads of farming, or even intensive rice-farming specifically, to Korea and Japan. So the full explanation has also to include recent unifying sociopolitical conditions overwriting presumed greater original diversity – as hinted at, for example, by the Ryukyuan

languages surviving in the southernmost islands of Japan.

South of Sinitic, meanwhile, *southernmost China and Mainland Southeast Asia* are home to various language families, much smaller but still significant regionally. These too are routinely (if also rather vaguely) attributed to the spread of agriculture – although here with rice as the key crop and putative homelands thus all within the wider Yangtze region instead. Again, however, the main expansion phases of most families of Mainland Southeast Asia are too recent for a direct association with the *first* spread of farming here – just as with the Sinitic and Mandarin expansions, and in fact not unconnected with them. For the general trend here is of expansion southward from homelands assumed to have been in southern China, whose now minority populations speak languages of the same lineages found across much of Mainland Southeast Asia, particularly Tai-Kadai (including Thai/Lao) and Tibeto-Burman. As so often, however, it remains unclear precisely what role was played by agriculture, among various other factors. Rich (rice-) farming lands such as the Mekong Delta may have been a key attraction, but that does not explain which particular populations (and their languages) came to enjoy the *wherewithal* to occupy them, at the expense of others pushed aside to become the "hill peoples" (notably the speakers of Hmong-Mien languages). In any case, perhaps more powerful than any such pull of the south was the push from the north: the pressure of a powerful and expansive Chinese culture and population.

The one family in Mainland Southeast Asia that does not seem intrusive from further north is Austroasiatic (including Khmer and Vietnamese). Estimates of its greater time depth are also rather more compatible with the *first* spread of agriculture here. Proponents of a farming/language dispersal (e.g., Higham 2002; Bellwood 2005: 214–216) even hypothesize that Austroasiatic enclaves as far west as the Munda languages in central *India* may be a linguistic footprint of how *rice* farmers expanded westward into the subcontinent, out of Indochina, or perhaps specifically along the course of the Brahmaputra, once across the watershed with the Yangtze. In India, they would ultimately be surrounded and far outnumbered, though, by speakers of the Indic branch of Indo-European, which that same general hypothesis identifies – very controversially – with cultivators of other cereals arriving from the northwest, ultimately from the Fertile Crescent (Renfrew 1987), as we shall shortly see.

Indic intruded also on the other main language lineage of the subcontinent, Dravidian, ousting it from much of its original range to confine it now largely to the southernmost third of India (save for a few intriguing outliers further north). That is, Dravidian is widely accepted as predating the arrival here of Indic. Much else about its prehistory remains unclear, however, not least whether and how Dravidian's expansion may itself in some way have been "driven" by agriculture. It has been variously attributed to local processes of domestication, or to a preceding stage of merely foraging for wild grains, or even to already developed farming arriving ultimately from the Fertile Crescent (for a discussion, see Fuller 2002). The "evidence" and interpretations behind each proposal remain questionable and much disputed. In particular, a link back to the Fertile Crescent is built upon a putative relationship of Dravidian to ancient Elamite, a claim generally dismissed by linguists. In short, we still know too little of Dravidian prehistory to tell whether it stands more as an illustration of a farming/language dispersal or a counterexample.

Most of *Northern Asia*, meanwhile, has over recent millennia been exploited by subsistence regimes very different to sedentary agriculture. In the far north and Siberia, hunting and gathering predominate, not least fishing and some domestication of reindeer (from perhaps around 3000 BP), albeit still principally to aid in tracking wild herds for meat. The Eurasian Steppe, meanwhile, formed the quintessential environment for nomadic pastoralism based around domesticated horses, although only reaching its famous heights in the last two to three millennia.

The linguistic picture across Northern Asia, too, is radically different to the rest of Asia. Arrayed very roughly from east to west – although also widely interspersed among each other – are first a cluster of minor "Paleosiberian" lineages

and then the four rather larger families of Tungusic, Mongolic, Turkic, and Uralic. Siberia and Central Asia do, then, attest to language expansions, and ones that over this vast landmass can appear impressive in their territorial ranges, at least. Yet in crucial respects – in speaker populations and time depth – they do not remotely approach the scale of the language families spoken across the agricultural heartland regions to their south and west. Alongside those, Mongolic and Turkic are of particularly shallow time depths of just a millennium or two. Moreover, for all their terrorizing of Europe and "elite dominance" conquests of China (the Yuan dynasty) and India (the Mughals), the *language* lineages of these steppe populations never significantly broke into those farming regions. Apparent minor exceptions turn out to be largely limited to similar steppe-type biomes in any case: the Great Hungarian Plain and the highlands of Anatolia.

Rather, the extreme mobility of these nomadic populations has left across Northern Asia a linguistic signal of a very different form. The "linguistic area" of North Asia attests not to a great expansion out of a single origin (the "Altaic" hypothesis, now increasingly discounted in linguistics), but to all but the reverse: intense interaction and *con*vergence between groups originally of different origins (Janhunen 1996: 237–242). Much of Northern Asia is home to environments where farming is either not viable at all (over much of Siberia) or only marginally so, at least for most of prehistory, and especially by comparison to the great success of horse-borne pastoralism on the steppe. In this sense, these regions fall by definition outside the scope of the farming/language dispersal hypothesis in any case, since agriculture did not generally become the dominant subsistence mode here until the modern period. This is also clear from these regions' relatively very low population density and thus the relatively small demographic scale of the language expansions here, however geographically extensive they may be.

The steppe does nonetheless bear directly on the farming/language dispersal debate in one sense, and indeed in one of the first and most controversial claims of all: Renfrew's (1987) invocation of the hypothesis to account for the existence of the Indo-European family, which includes the native tongues of a far larger share of the world's population and land area than any other. The leading traditional theory (see Mallory 1989) had instead long imputed Indo-European's expansion to warlike, horse-borne and (semi-) nomadic populations spreading out of the steppe, and specifically in this case from the Pontic-Caspian area. The estimated time frame was around the sixth millennium BP, that is, at least three millennia earlier in the trajectory of pastoralism than any of the known historical conquests. Most language data have traditionally been held to support such a vision, in geography, chronology, and even a supposedly key role for the horse. Yet the "laws" that allow us to reconstruct the ancestor language on the level of sound do not extend so reliably to precise meanings, so any supposed referents in "Proto-Indo-European culture," such as the wheel or *domesticated* horse, are much more a matter of subjective interpretation. Recent (and likewise disputed) Bayesian analyses of the Indo-European family's linguistic phylogeny, meanwhile, favor an origin in central/eastern Anatolia – that is, the northern arc of the Fertile Crescent – and at an earlier time depth in line with the expansion of agriculture (Bouckaert et al. 2012). Moreover, as just observed, the many historical cases of elite dominance by steppe pastoralists all signally failed to carry their *languages* durably into neighboring farming lands. And where they failed, it may seem questionable that "Kurgan" pastoralists of the fourth millennium BC could on the contrary have succeeded so spectacularly, to impose their speech across so much of Europe, India, and many lands between. Expansion by demic diffusion with the spread of farming at least seems an explanation more commensurate with the scale of the striking linguistic outcome that Indo-European calls upon us to explain.

Indo-European is an early test case and illustration of how ancient DNA can transform our understanding of how the genetic, linguistic, and archaeological records relate to each other through prehistory. The first major results supported a large-scale demographic replacement

(70% or more) into the Corded Ware regions of Northern Europe in the early Bronze Age, by an incoming population from the Yamnaya culture on the Pontic-Caspian steppe (Haak et al. 2015). This was initially taken as strongly favoring the steppe pastoralist hypothesis for Indo-European, although now by "massive" demographic impact rather than by elite dominance, as previously argued. Further findings suggest that the demographic turnover may reflect not (just) subsistence factors, but the concomitant introduction of an early form of the plague pathogen (Rasmussen et al. 2015).

The date range for this migration from the steppe is 4800–4500 BP, however, uncomfortably shallow for the Indo-European family as a whole. Indeed the actual claim was that it may explain "at least some" branches of Indo-European "in Europe" (geographically, the most straightforward candidates would be the Balto-Slavic and/or Germanic branches). Moreover, steppe ancestry is equally high in speakers of Uralic languages (unrelated to Indo-European), also in northeastern Europe. In many other branches of Indo-European, meanwhile, the steppe component turns out to be very low or absent. Mycenaean Greeks were still, in genetic terms, very dominantly of the "European first farmer" type (Lazaridis et al. 2017), as were the best candidate populations for having spoken languages of the extinct Anatolian branch of Indo-European. On the Zagros side, meanwhile, the "Eastern Fertile Crescent" genetic type is significantly different, but has been tentatively identified with the Iranic and Indic branches of Indo-European spread eastward with farming (Broushaki et al. 2016). Intriguingly, this "Eastern Fertile Crescent" genetic profile is a good candidate also for the component that spreads onto the Pontic-Caspian steppe during the seventh millennium BP, to make up roughly half of the genetic profile that later spread from there into the Corded Ware region of Europe. In sum, ancient DNA has significantly advanced the debate between the rival farming and pastoralist hypotheses for Indo-European – but it brings support only for parts of each hypothesis and full support for neither. As outlined here for several other language families worldwide, Indo-European too may turn out to be a complex hybrid story that includes major secondary developments and expansion stages, within the overall story of the spread of food production in its various forms (Heggarty forthcoming).

Island Southeast Asia and the Pacific

Ever since the early days of the hypothesis, *Island Southeast Asia and the Pacific Islands* have been hailed as a prime illustration of a farming/language dispersal. It is certainly striking how just a single-language family – Austronesian – is so disproportionately dominant here. No less conspicuous, though, are the glaring exceptions to that dominance: New Guinea and various neighboring islands in Melanesia, not to mention Australia.

There is now little dispute that Austronesian dispersed out of a homeland in Taiwan, through the Philippines and across Island Southeast Asia, and ultimately throughout Polynesia as far as New Zealand, Hawaii and Easter Island. The broad direction, scale and time depth of the *language* expansion are clear and cannot be overturned by the original arguments from genetics for a "slow boat" expansion out of Wallacea instead, some ten millennia earlier – a scenario that fits neither the time depth nor the structure of the Austronesian family. Those do indeed seem to fit only with a "fast boat" out-of-Taiwan model – see, for example, Gray et al. (2009). In archaeology, meanwhile, Taiwan is widely claimed as at least the main source from which farming too, over similar timescales, spread into Island Southeast Asia and the Pacific. Many have made the direct match with Austronesian, and the general hypothesis has fared relatively well here.

That said, lively debate continues on quite how significant was the contribution from Taiwan on levels other than the linguistic. How important to the overall agricultural "package" here were other plants (and animals) domesticated elsewhere in the region (Donohue and Denham 2010)? How much did Austronesian spread by immigrant farmers outpopulating the locals, or by native populations simply switching language to it? And agriculture aside, how critical too was the development of very sophisticated seafaring

technology and navigational skills? Were not these, more than farming, the limiting factor in determining which particular population group (i.e., speakers only of the Proto-Malayo-Polynesian sub-lineage of Austronesian) would expand so spectacularly, when other nearby farming populations did not?

The hypothesis also seems to leave unexplained the case of *New Guinea*: for agriculture did develop here, yet the island ranks as the most diverse place on earth in its count of independent language lineages. Much remains unclear, however, not least on the nature of early farming here, how and when it arose, and on putative "big picture" classifications of these most under-researched languages of the world. The "Trans-New Guinea" hypothesis, notably, would bring a significant proportion of the island's language lineages, especially through its mountainous interior, into one large family (though still leaving dozens of others). Advocates of "Trans-New Guinea" as a linguistic construct, and of the general farming/language dispersal model, have accordingly both seized on the potential match between the linguistic "effect" and the rise of agriculture as its potential cause: see, for instance, Pawley (2005: 95–102) and Bellwood (2005: 231–232), respectively. Just how much the New Guinea case may either challenge or even support the farming/language dispersal hypothesis, then, hangs on many unresolved issues. The mix of potential explanations for language prehistory here includes a host of other factors too, not least on the environmental and cultural levels: for instance, the long isolation between human groups here, given the tortured mountain topography and apparently endemic warfare.

Australia is entirely different again, for here farming never arose in any case. The continent is thus relevant to the debate only in a negative or indirect sense and from either of two very different perspectives. On the standard majority view, almost all indigenous languages of Australia form a single large family, dubbed "Pama-Nyungan." This covers the entire continent save for most of the "Top End" of northernmost Northern Territory, which is much more linguistically diverse, and perhaps Tasmania, whose vanished native tongues are simply too little known to classify at all. Pama-Nyungan would thus imply a territorially significant language family expansion, estimated to date back five millennia or more, only here without farming (and thus relatively small in demographic scale). This is sometimes invoked as if to challenge the idea of farming/language dispersals, yet that is greatly to misconstrue a hypothesis that by definition simply cannot apply to regions and time periods without agriculture in any case, and can make no claim to explain language dispersals there.

On a minority alternative view, meanwhile, the linguistic panorama of Australia is not to be interpreted in terms of one dominant and *di*vergent "Pama-Nyungan" language family at all, but as an area of long-standing linguistic *con*vergence instead. Dixon (1997) sets this also within his wider "punctuated equilibrium" model of language prehistory. The "punctuations" are episodes in which just a few major language families were somehow propelled to expand across large parts of the world, overwriting a greater underlying linguistic diversity. Farming would rank among the plausible causes of such punctuations (Dixon 1997: 77–78). Australia, then – in Dixon's minority view – would then be an instance of the linguistic outcome *without* the "punctuation" impact of the Neolithic.

Africa

In Africa, agriculture is invoked to account for the two main language family dispersals, independently across the north and sub-Saharan parts of the continent – though in the former case, the proposal remains much disputed.

Berber, ancient Egyptian, and many languages of the Horn of Africa all go back to the dispersal of the "Afro-Asiatic" language family. The *Asiatic* half of its name, meanwhile, refers to the family's lone branch outside Africa, confined moreover to *Western* Asia, in the form of the "Semitic" languages, today most notably Arabic. The Levant is also where the farming/language hypothesis puts the origin of the entire Afro-Asiatic family, with the Natufian and Pre-Pottery Neolithic B populations (Militarev 2002). Not that this hypothesis enjoys any consensus; it is but one of

a number of equally disputed proposals (e.g., Ehret 2002: 35–39), which point instead to homelands in various regions beyond the Red Sea in Africa itself, and to a range of time frames before farming here. Without agriculture, though, these alternative hypotheses do struggle to find plausible explanations commensurate in impact with the scale of the vast linguistic legacy that is Afro-Asiatic.

The Bantu language lineage, by contrast, is often held up as a paradigm case of a farming/language dispersal, more widely accepted even than in the case of Austronesian. Certainly, much of the linguistics is undisputed: out of a homeland in the Nigeria/Cameroon region, Bantu has over the last three millennia or so spread to dominate most of southern and eastern Africa. Zulu and Swahili, for instance, are just two among hundreds of related languages within a vast Bantu "dialect continuum." Correlations have been widely proposed with the spread of farming and ironworking, and indeed with signals in human population genetics. Data from these various disciplines have increasingly been brought together (e.g., by Filippo et al. 2012) to argue even for particular paths of expansion and for "demic diffusion" as the mechanism by which it proceeded, as per the initial formulation of the farming/language hypothesis (Renfrew 1987: Chapter 6).

The few other and much smaller language lineages found in southern and eastern Africa – particularly San and Khoi in the far southwest and Hadza and Sandawe in Tanzania – are now largely isolated and endangered and seem clearly to represent rare survivals of whatever language lineages were spoken before Bantu spread into the region. Contrary to early, outdated hypotheses, there is no good case at all that these various "click" language lineages are related to each other, whatever their speakers' deep genetic inheritances may be. For a survey of these questions and the exact nature of the impact of the Bantu advance on the Khoi pastoralists and their own migrations, see Güldemann (2008).

Yet while Bantu seems a clear-cut case, again it remains just one part of a far wider dispersal, beginning some millennia earlier: that of the great "Niger-Congo" family to which Bantu belongs. What drove that initial dispersal? If that too was farming, then how could that one explanation account for these two dispersals at very different time depths? Do they represent different stages of intensification? Or rather, was it not farming alone that lay behind the Bantu spread, but the crucial extra ingredient of ironworking?

The Americas

The far north of *North America*, where farming was not viable at all, is nonetheless filled by three language families spoken by hunter-gatherer groups, and certainly widespread, albeit demographically very thinly: Eskimo-Aleut, Algic (mostly Algonquian) and Na-Dene. Any candidates for farming dispersals can only lie further south. Bellwood (2005: 244–250) does venture claims to this effect over parts of the eastern USA, but our knowledge of pre-Columbian language distributions here is very patchy and suggests a relatively fragmented pattern of various language lineages, rather than any single predominant one. Moreover, farming itself here developed relatively late and never became so intensive as in the two main and much earlier hearths of agriculture in the Americas, both further south.

In *Mesoamerica*, the hypothesis has often been invoked but remains highly controversial, especially in the case of the Uto-Aztecan family. As its name embodies, this has one foot in the Mesoamerican heartland (not least in the form of Nahuatl or "Aztec") but another in southwestern USA (e.g., as Ute, whence also the name Utah). Standard linguistic thinking (see, e.g., Kaufman and Justeson 2009) has long assumed that the family's ancestral language was spoken by originally forager populations along the western reaches of what today is the US-Mexico border, though without a convincing explanation of how they also came to penetrate deep into the Mesoamerican heartland. One rival (though much disputed) interpretation of the language data, however, fits instead with a dispersal northward out of a Mesoamerican homeland, together with maize farming (Hill 2002). It thus has also to envisage Uto-Aztecan speakers ultimately reverting to foraging as they spread northward into environments much less suited to farming.

For the other main language families of Mesoamerica, firmly within the core farming region, the hypothesis is rather more widely entertained (for references, see Bellwood 2005: 237–239), notwithstanding continuing objections (Campbell and Poser 2008: 345–346). Certainly, the Mayan and Otomanguean families appear to go back to quite different time depths, so if both were farming dispersals, then some explanation is required (again, perhaps different stages in intensification). Also, although the main language families of Mesoamerica (and indeed the Andes, see below) remain significant in speaker numbers by the standards of most indigenous language lineages of the Americas, they still pale alongside the vast Old World language families. In large part this reflects the devastating mortality wrought on their speaker populations by Old World pathogens in the decades after 1492, and centuries of language shift in favor of European tongues ever since. Yet even allowing for this, at their peak the main indigenous language families of Mesoamerica were still minnows in Old World terms, not only in demographic but also in geographical scale. The farming/language dispersal hypothesis would presumably have to impute this to the much more gradual way in which agriculture came to be incorporated into subsistence regimes here, together with other peculiarities such as the lack of large domesticated animals, and indeed environmental constraints. For agricultural expansion out of Mesoamerica clearly did face considerable obstacles: in the arid climates immediately to its north and the constriction of the isthmus of Panama to the south.

Amazonia constitutes, after New Guinea, the world's other main hotspot of language lineage diversity, also all too thinly researched and sketchily understood. Far from presenting some single-language family expansion able to exclude all others, the region presents a striking linguistic mosaic. There were certainly some major family expansions here – Arawak, Carib, and Tupí, as well as Jê more in the savannah zone to the southeast – but each far less continuous than the great Old World spreads like Indo-European, Sinitic or Bantu. The main Amazonian families do range far and wide, but their distributions are unusually fragmented, scattered, and interspersed both with each other and with many other minor families and isolate lineages. Many hypotheses on where the main families originate point to the upper reaches of the Amazon Basin, that is, the foothills of the Andes where farming too is widely taken to have originated. For Arawak and Tupí particularly, farming/language dispersals are regularly invoked (see, e.g., Dixon and Aikhenvald 1999: 16–19) – farming, that is, at least in one form or another, given how agriculture here followed a very different trajectory to the Old World. It often took the form of shifting slash-and-burn, and in many regions such farming continued to coexist with hunter-gatherers, often occupying riverside territories vs. the rainforest interior, respectively. Moreover, complementary or rival explanations are also invoked, not least one factor promoting mobility over great distances here: the relative ease of moving along the region's great watercourses – and especially *down*river, i.e., ultimately also from (farming) homelands around the periphery of Amazonia.

In the (Central) *Andes*, a particular set of environmental constraints again shaped the very independent development of farming and civilization here. This key hearth of agriculture (not least of tubers) seems at first sight a counterexample to the farming/language hypothesis, for it conspicuously fails to exhibit any major language expansions at a time depth commensurate with the very early beginnings of agriculture here. On closer inspection, however, the Andean case tends rather just to underline the refinements and qualifications that must attend the hypothesis if it is to be applied across regions of the world where farming itself arose so differently and over such contrasting trajectories through time. In the Old World, farming is effectively defined by certain key components present right from the start: cereals and large domesticated animals for both traction and (mobile) protein. Both were glaringly absent in the Andes until millennia after agriculture first began here. Environmental hyperdiversity through 6500m of altitude variation, and within the tropics, also much delayed crop adaptations, while on the Pacific coast the world's richest seafood resources underpinned subsistence so reliably that societies

here were raising monumental architecture even before they were heavily reliant on farming at all. Thresholds in the *intensification* of farming and their concomitant demographic and sociocultural impacts followed a chronology quite unlike that of the Old World and may not after all be so incompatible with the relatively recent major language family expansions here (Aymara and Quechua). The Andes are a good illustration of how the wider debate on the farming/language dispersal hypothesis would do well to be sensitive to a range of necessary refinements – as summarized in ▶ "Farming-Language Dispersals (1): Principles" and explored in more depth in Heggarty and Beresford-Jones (2010).

Farmsteads and Rural Life in the United States, Archaeology of

Mark Groover
Department of Anthropology, Ball State University, Muncie, IN, USA

Introduction

The historical archaeology of farmsteads and rural life investigates the development of agriculture in North America from the 1500s to the 1900s. The topic emerged in the 1970s due to the large number of rural sites and farmsteads routinely encountered during cultural resource management (CRM) archaeology projects in the United States. Rural sites are important archaeologically from a cultural and historical perspective because the majority of North American households practiced farming until the twentieth century. A rapidly declining way of life, today a small proportion of the American population pursues farming as an occupation. Consequently, archaeologists emphasize that it is important to materially document the cultural trajectory of this significant aspect of American life.

Definition

The archaeology of rural life and farmsteads examines the material culture and social history of farms from the 1500s to the 1900s in North America. Several relevant topics are typically addressed archaeologically at farmsteads, such as the landscape and architectural history of the farm, the standard of living that the residents experienced based upon the type of agriculture they practiced, and the types of economic strategies pursued at farms. The ways that production regimes over time may have influenced the built environment and household material life, such as the transition from subsistence to commercial farming, are often addressed in farmstead research. The influence of progressive, modern farming practices upon rural life is also explored in farm studies, in addition to the effects of consumerism upon farm households. Social and cultural questions are also explored in farmstead studies, such as the effects of place of origin, nationality, and ethnicity upon agricultural practices. Changing gender roles in farm families and the effects of race and inequality in rural contexts are also addressed.

Historical Background

The archaeology of farmsteads and rural life examines material culture trends that occurred during the colonial, antebellum, and post-bellum/modern periods in US history. Paralleling this time span, the transition from folk, vernacular-based regional cultures to national-level industrially influenced consumer culture is a major topic of inquiry in material culture research. Consequently, farm studies and the examination of rural life in general are well suited for exploring the timing and extent of this transition from folk to industrially based culture in different parts of the United States between the 1500s and the 1900s. The transition from producer-consumer households to predominantly consumer households can also be addressed via archaeological studies of rural life. The archaeology of colonial period farms (c. 1500s to 1780s) often focuses upon small, vernacular-oriented settler farms that practiced self-sufficiency and subsistence-level agriculture. Log houses and timber frame post-in-ground dwellings were prevalent during this

period in eastern North America. Artifact assemblages from farms of this period often contain kitchen and food related items and a much smaller amount of personal or household-related artifacts. Between the late 1700s through the mid-1800s, farms became increasingly profit-oriented and emphasized efficiency in farming and production maximization. Consequently, the domestic landscape and built environment at antebellum farms (c. 1790s to the 1860s) are usually more structured and planned than farms dating to the preceding colonial era or settler periods in different regions (Groover 2008). Likewise, as farms began to practice commercial production, the amount of factory-manufactured consumer goods recovered from farm sites often increases dramatically. During the post-bellum/modern period from the 1870s to the 1900s, farms increasingly incorporated new technology into their operation, revolutionizing agricultural production and rural life in many regions of the United States. Likewise, consumerism that began in the 1800s continued in rural locations during the twentieth century. The challenge for contemporary historical archaeologists is to effectively reconstruct the primary material trends that occurred among rural households as the transition from noncommercial to commercial-level farming transpired in different regions of the United States.

Key Issues and Current Debates

Key issues and debates in farmstead archaeology center upon interpreting the significance of rural sites encountered during CRM archaeology projects. Since the 1970s, a minority of archaeologists have argued that farmstead sites represent a very prevalent, redundant, and hence expendable type of archaeological resource that consequently should not be preserved or studied archaeologically, given the amount of written information regarding farm life in the United States. In contrast, most contemporary historical archaeologists recognize that farmsteads are a very important research topic and type of cultural resource. The archaeological research significance of farmstead sites is based upon the information potential that farmsteads offer to archaeologists. Significance is also based upon the current state of knowledge related to farmsteads in a specific region, depending upon the types of farm sites previously investigated and the range of questions addressed at these sites.

An important element of farmsteads in the significance debate is that farmsteads, often occupied by several generations in the same extended family, usually possess considerable time depth, having been occupied for at least a century or more. Because of their characteristic time depth, farms represent relevant "time laboratories" where archaeologists can explore long-term material trends related to the archaeological dynamics of continuity and change in domains such as the domestic landscape, architecture, economic strategies, foodways, and household material culture within an extended family. Previous studies have demonstrated that landscape change and material consumption and deposition, particularly of foodways related items, are significantly influenced by the life history and family cycles of the farm residents (Groover 2003, 2008). Due to the time depth often associated with farms, they represent significant archaeological resources and an important context for exploring medium-term material trends.

International Perspectives

The systematic study of farmsteads internationally is beginning to develop in different parts of the globe. International studies of farming households and landscapes (e.g., Morrison 1991; MacDonald Lake and Edwards 2006; Tarlow 2007; Carroll 2011; Prossor et al. 2012) dating to the past 500 years are very relevant and valuable because they illustrate the range of variation in agriculture throughout the world. Archaeological studies have been conducted in England, Ireland, and Australia at farmstead sites dating from the late medieval period to the nineteenth century (e.g., Barnwell and Giles 1997; Brunskill 1999; Dalglish 2003; Atkinson 2010; Orser 2010). For American archaeologists, international farm

studies can highlight the origins of farming practices that were transplanted to and modified in the United States. Using migration as a primary analysis topic, farm studies in the United States often emphasize the ethnic practices and place of origin of farm residents. Origin studies attempt to establish what material practices were reestablished in the New World and how agricultural practices and material traditions may have changed over time.

Future Directions

As the number of farmstead studies increases in the United States and elsewhere, a pressing challenge for historical archaeologists is to systematically synthesize new information into a coherent state of knowledge regarding the trajectory of rural life in different regions over time. This task is particularly necessary for future archaeology projects supported by public funds. Evaluating the significance of farmstead sites is based on establishing the context of the site and determining the research potential of encountered farmsteads. The research potential of specific farms can be established through reference to a current state of knowledge in a given region. Simply put, the current state of knowledge, especially in cultural resources management, refers to the existing body of information related to a topic and existing questions that should be addressed by future site studies. Unfortunately, in the United States, an overarching, systematic synthesis of farmstead archaeology based on previous studies is yet to be conducted. However, many archaeologists have conducted regional-level studies of rural trends in specific geographic areas over time.

Fedorov-Davydov, German A.

Marina D. Poluboyarinova
Institute of Archaeology at Russian Academy of Sciences, Moscow, Russia

Basic Biographical Information

German A. Fedorov-Davydov was born on July 17, 1931 and died on April 23, 2000. He was a doctor of historical sciences, a professor, a corresponding member of the German Archaeological Institute (1983), a member of Academy of Natural Sciences (1993), and the winner of the Lomonosov Award of the first degree of Moscow State University (1998).

His father was a professor at Moscow State University and a famous Soviet art historian. His mother was an artist.

After leaving school in 1949, he joined the history department of Moscow State University, where he majored in the department of archaeology. As a student, he participated in the Khorezm expedition and wrote a thesis on "The Mint minted Khorezm in XIII-XIV centuries" (head – Professor S.P. Tolstov).

From 1954 to 1956, he was a postgraduate of Moscow State University Department of Archaeology (supervisor – known Soviet archeologist A.P. Smirnov). In 1957 he defended his thesis on "The Treasures of Coin the Golden Horde (main stages of development of currency and monetary-weight systems in the Golden Horde XIII-XIV centuries)."

In 1956–1960 G.A. Fedorov-Davydov worked in the Institute of History of Material Culture – Institute of Archaeology of Academy Science of the USSR (in 1958–1960 he was executive secretary of the journal "Soviet Archeology"). From 1960 until his death, he was working at the Department of Archaeology of the History Department of Moscow State University (since 1960, the assistant; since 1962, associate professor; since 1969, professor). G.A. Fedorov-Davydov defended his doctoral thesis entitled *Nomads of Eastern Europe in the X-XIV Centuries* in 1966 at Moscow State University.

Major Accomplishments

The scientific interests of G.A. Fedorov-Davydov were extremely wide: medieval archaeology of the Eurasian steppes; history, archaeology, and numismatics of the Golden Horde; the ancient and medieval art of the Eurasian steppes; ancient and medieval culture of the Volga; currency and trade in the Northeast; statistical methods in archaeology; and relationships and civilizations of the East and West in the context of the history of the Silk Road.

He lectured on "Fundamentals of Archaeology" and "The Historiography of Archaeology" and conducted special courses: "Archaeology of the Volga Region," "Archaeology of Central Asia," "Archeology and Culture of the Muslim Countries," and "Statistical Methods in Archaeology" at the Department of Archaeology of the Moscow State University. Among G.A. Fedorov-Davydov's students, there are known archeologists of Moscow, including Kazan, Saransk, Volgograd, Astrakhan and Dagestan, Azerbaijan, Uzbekistan, and Tajikistan.

G.A. Fedorov-Davydov participated in many archeological expeditions that took place from 1950 to 1990 (Central Asia, Ukraine, the Middle and Lower Volga Region, Mongolia, Tunisia). In 1970–1990 he led the Institute of Archaeology of Academy of Sciences and Moscow State University expedition in the Volga Region.

The most significant scientific accomplishments of G.A. Fedorov-Davydov concerned research related to the Golden Horde city. Since 1959, he led the research in Tsarevskoe, Selitrennoye, and Vodyanskoe sites. He detailed stratigraphy of the excavated sites and specified the time of death of the Golden Cities. The archeological materials were summarized in the monograph "Golden Horde cities of the Volga region" and in his books and articles published abroad.

One of the most striking episodes in the career of G.A. Fedorov-Davydov was the discovery of the burial ground with masterpieces of ancient art at Kosik in 1984.

His theoretical works, illustrated by methods of mathematical statistics, were of great importance for the development of Russian archaeology.

G.A. Fedorov-Davydov did a lot of research, organization, and socializing; he is the author of about 230 scientific and popular-scientific works, including 26 books.

Ferguson, T. J.

Chip Colwell
Editor-in-Chief, *Sapiens*, New York, USA

Basic Biographical Information

T. J. Ferguson (b. 1950) is a luminary in the global movement to make archaeology more relevant to and respectful of Native American communities. He has been particularly instrumental in issues surrounding repatriation, the development of tribal cultural resource management (CRM) programs, and the advancement of an applied archaeological paradigm that bridges different elements of anthropology and the humanities to understand native peoples past and present.

The son of a career military officer, Ferguson spent his high school years in Oahu, Hawaii, and graduated with a bachelor's degree in anthropology from the University of Hawaii at Hilo in 1973. Ferguson went immediately into graduate school. After receiving his master's degree in

anthropology from the University of Arizona in 1976, he planned to return to Polynesia but instead accepted a job at the Pueblo of Zuni in New Mexico. Through that work he became interested in historic and cultural preservation, and land claims, and would come to spend his career (to date) focused predominately on the American Southwest. After the position at the Pueblo of Zuni, Ferguson went back to graduate school to pursue a master's of community and regional planning, which he received in 1986 from the University of New Mexico. He would later earn a Ph.D. from the University of New Mexico in 1993 – with a dissertation using an archaeological application of space syntax to illuminate historic Zuni architecture (Ferguson 1996a) – while also working as the Director of Southwest Programs at the Institute of the North American West. Following this position, Ferguson established his own companies (first with Roger Anyon) in which he could pursue applied research. He is currently the owner of Anthropological Research, LLC, and a Professor of Practice at the University of Arizona.

While working for the Pueblo of Zuni, in 1978, Zuni religious leaders decided to seek the return of stolen *Ahayu:da* (War Gods). Ferguson became part of the Zuni team that eventually would recover virtually every known War God in a US public institution (Ferguson et al. 1996). Their success helped lay the groundwork for US repatriation law and the global repatriation movement. In the years since, Ferguson has worked for both tribes and US federal agencies to conduct cultural affiliation studies, which provide a vital legal pathway for cultural items to be returned from museum repositories and archaeological sites. He has actively contributed to the academic and intellectual debates about cultural affiliation and other issues relating to repatriation (e.g., Ferguson 2003, 2004). He has also served as a member (2005–2013) of the Smithsonian Institution's Repatriation Review Committee.

In 1976, Ferguson became the Assistant Director of the Zuni Archaeological Enterprise – the first tribally run cultural resource management firm in North America. The next year, when the program reorganized, he became the Director of the Zuni Archaeology Program. Through these efforts, Ferguson and his colleagues demonstrated the value of archaeology for tribes and thus established a framework for heritage management conducted by tribes (Ferguson 1984). Since then, dozens of tribal CRM programs have been established, as well as more than 100 Tribal Historic Preservation Offices.

Major Accomplishments

The experiences at Zuni provided a basis for Ferguson to build a career around using archaeology to serve tribal needs and interests. He has developed a unique brand of archaeology that spans an array of anthropological and humanistic approaches that include ethnohistory, ethnography, and geography (e.g., Ferguson and Hart 1985). Many of his projects have directly supported tribal welfare in the domains of cultural preservation and land and water rights. For example, he has served as an expert witness for the Pueblo of Zuni, successfully helping them in their decade-long land claims case as well as their efforts to protect the sacred Zuni Salt Lake; he has conducted research for the Pueblo of Taos to successfully prevent the impacts of a proposed airport expansion on the tribe; and he has helped the Pueblo of Laguna successfully have the sacred Mount Taylor acknowledged as a traditional cultural property under New Mexico state law. Much of his applied work involves the documentation of traditional cultural properties that are potentially threatened by development projects through the Section 106 process of the National Historic Preservation Act, but he has also collaborated on projects that proactively study tribal histories, such as a National Science Foundation study to document Hopi place names.

Over a three-decade plus career, Ferguson has thus shaped a research agenda that demonstrates how archaeology can be conducted by, for, and with Native Americans. While much of his applied work has led to a long list of technical reports, Ferguson has been a regular, vocal, and intelligent contributor to the discipline's ongoing discussion about its relationship with

indigenous peoples (e.g., Ferguson et al. 1993; Ferguson 1996b, 2009). He has also greatly advanced these efforts through service to the discipline, holding a range of positions in professional organizations, most notably serving on the Executive Board of the American Anthropological Association (2007–2010). His contributions to archaeology have been recognized through numerous awards, including the Society for American Archaeology Presidential Recognition Award in 1997 for his work bridging archaeology and Native views and the Solon Kimball Award for Public and Applied Anthropology in 2006 for developing models of mutually beneficial collaboration between American Indian communities and archaeologists in field research, museum practice, and assessments of cultural landscapes.

Field Method in Archaeology: Overview

Martin Carver
Department of Archaeology, University of York, Kings Manor, York, UK

Introduction

Most archaeological research depends, directly or indirectly, on information recovered in the field, primarily as a result of campaigns of *survey* and *excavation*. The way field projects are designed, implemented, analyzed, and published is summarised here and reviewed in a number of case studies (see "Cross-References").

Much of the *archaeological resource* is vulnerable to disturbance from the exigencies of modern life, and may be destroyed through the construction of roads (motorways) and buildings, especially in towns. Even in open country and desert, the surface is subject to continual attrition. Archaeological

investigation therefore demands work to be of the highest quality and precision, designed to maximize information while it is still detectable and wherever possible to conserve deposits in the ground. While much field method is directly applied to research questions, much more effort goes in recording archaeological sites that are likely to be damaged by modern construction or clearance. This work is undertaken by the rescue or commercial profession (said to be engaged in *CRM* or Cultural Resource Management). At the present time, CRM activity greatly outnumbers university activity in both in its staff and their budgets.

Definition

Field archaeologists explore the past at a number of different scales and use a basic vocabulary to designate what they find. The basic unit of past activity is the *object*, which might be an *artifact* (man-made – e.g., a brooch) or an *ecofact* or biota (natural- e.g., a seed). A collection of such objects is an *assemblage*. The earth or mineral *deposit* from which an assemblage is retrieved is a *context* (also called a stratum, a stratigraphic unit, or a cultural layer). Any set of contexts which offers evidence for past activity is a *feature* – a general term of great use in archaeology since it so often happens that we find something but do not yet know what it is. A wall, a grave, a path are examples of features. A set of features, like four walls, can be designated as a *structure* (e.g., a building). A *site* is the term used for a concentration of features, which imply former human occupation. It is also used to denote a place at which archaeologists have focused their investigations. A *landscape* (or *historic landscape* or *historic environment*), in archaeological terms, is compounded of the detected parts of ancient land use, particularly sites.

Key Issues/Current Debates/Future Directions/Examples

Archaeological investigation is a science that responds to the needs of research, to the way that information has survived in the ground and to the present ownership and stakeholders of the site or landscape in question. Research objectives, terrain, and the social context therefore have to be matched for every field project in a *project design*. The best known methods of field investigation are survey, which reviews large areas on the surface (extensive investigation); excavation, which examines a constricted piece of ground by dissecting it (intensive investigation); and building recording, which deduces the history of buildings that are still standing. Modern projects, whether applied for pure research or for CRM, use all these in combination in rigorously planned programs (Carver 2009, Chap. 14).

Investigative Procedure

Field investigation typically takes place in six consecutive stages, each of which deploys a range of different methods, described in more detail below (see Table 1).

1. The object of *RECONNAISSANCE* is to explore ancient landscapes and identify sites, the site used in this case to denote areas likely to contain concentrated remains of earlier human activity. Methods of finding sites include *aerial archaeology*, using satellites, airplanes, or balloons as platforms to capture images of features that are often only visible or most visible from the air. *Surface investigation* involves walking over the surface of the ground and recording the artifacts that lie on the surface. Sites are located by mapping concentrations of objects as they lie. *Subsurface investigations* use geophysical or geochemical prospection, where anomalies picked up in, or under, the surface are mapped to show the traces of now vanished walls, roads, pits, and an increasing variety of other features.
2. An area suspected of containing buried information is designated as a site and then subject to *EVALUATION* to determine the best course of further action. The object of the evaluation is to supply as much information as possible to the design (which constitutes the subsequent stage). Predicting what lies under the ground is the first task, the result being reported as *deposit model*, showing the depth and character, and if possible the date, of the strata

encountered. The research objectives and the social factors affecting further investigation are also assembled at the evaluation stage. This part of the investigation is undertaken inflicting as little damage as possible, using the techniques of *subsurface investigation*. But many sites require small-scale digging to give a preview of what lies beneath; these include *shovel testing* (small shovel sized pits), *test pits* (square pits, usually 1 × 1 m in plan), or *test trenches* (cuttings between 1 and 2 m wide) (Hester et al. 1997).

3. *DESIGN* is the principal stage of field procedure, because it is at this point that the future of an identified site is decided. The importance of design is threefold – first it determines the agreed purpose of research and its outcome; secondly it determines the desired measures for the conservation of the site; and thirdly decisions taken at the design stage are often irreversible, particularly those that involve digging. A project design is a comprehensive document that incorporates and justifies a research program, a conservation program, and a program for continuing interaction with the public and stakeholders. The research program includes costed plans for survey, excavation, building recording, their anticipated outcome, the likely program of analyses (see below), and the plans for publication. Within this program are included the sampling strategies, itemizing the number, size, and location of areas to be surveyed and excavated. The conservation program includes measures for the long-term protection and management of the resource. The program of public interaction includes plans for display of the site and for serving the requirements of local ownership.

The project design provides the basis for funding and for permissions as well as the document that shows how the academic research agenda is to be addressed. Since there are many interested parties here, not only local, it follows that in modern professional practice, the project design will be published before implementation, allowing "multi-vocal" responses from a wide constituency. These responses will be incorporated into the agreed programs confirmed by the representative and funding bodies.

Since the project design is intended as an agreed contract between the field researcher and society, it is generally not varied until it has run its course, when another agreed

program may supersede it. In some parts of the world, the old "seasonal" system still endures, whereby the archaeologist redesigns the project every year. However, this would now be considered as less ethical than conforming to an agreed design-led package. The procedure for reviewing and accepting designs is appropriate to both university research and CRM reactive fieldwork, though there will be some variations between them. For example, while both should have research and management plans, CRM will often omit plans for public display.

4. *IMPLEMENTATION* is the active execution of the agreed programs. Using *survey*, *excavation* and *building recording*, and other bundles of techniques where appropriate, the implementation stage is usually performed in intensive seasons of fieldwork, using a range of crews stretching from two or three professional surveyors to a workforce of 50 or more volunteer excavators. The business of this workforce is to execute the study of the landscape or site on the ground and create records of what was measured, seen, or sensed, together with samples of materials encountered. The strategy for *Recording and Sampling* is laid out in project design, and is determined by the research objectives and terrain (see below). Many countries have laid down standard procedures for surveying, digging, and recording, although these are not helpful when they reduce creative observation, and thus the potential of the fieldwork to generate new knowledge. Site records have evolved over the last 20 years to capture observations at a number of different levels: primary data, agreed in advance and captured on proformae (for example, context records), interpretative definitions, using common vocabulary to describe interpretations on the ground (for example, using feature records) and metadata, which record the course of the field work, the circumstances of locality and weather, the crew, interim assessments, and numerous other matters; this information is traditionally captured in journals, photographs, and audio and video files.
5. *ANALYSIS*. Records made during fieldwork are examined at the analysis stage, with a view to understanding the results. Both survey and excavation usually generate large assemblages of objects, and detailed spatial records relating to objects, contexts, and features. The three main parts of the analytical program are: assemblage, *space*, and *sequence*, which together result in a narrative of what happened in the area examined.

The *assemblage* comprises all the objects and materials that are kept for analysis. The yield of an assemblage has been greatly increased by screening (sieving) the dirt, which helps to capture small objects that may be missed. Dry soil may be dry-sieved, and wet cloddy soil wet-sieved, i.e., broken up with water. The size of the mesh depends on what we want to find and varies from 1 mm for beads and potsherds to a few microns for pollen. New science is hugely increasing the range of what we can learn from the ground, by examining microscopic remains such as seeds, pollen, insects, and residues in pots. The study of *artifacts* usually requires the determination of its fabric (what it is made of), its form (implying its use), and its style (suggesting its cultural affiliations). Routine study of *stone, metal, ceramic, wood, leather*, and *textile* objects is well developed. The biota (biological fraction of the assemblage) includes the *soil, animal* and human remains, *seeds, pollen, phytoliths*, and other plant remains and insects. Parts of the assemblage are particularly valuable for their indications of date, for example, coins, which are provided with a date of minting and circulation by *numismatics*. The single most important method of scientific dating used routinely by field archaeologists is *radiocarbon dating*, which determines the date at death of organic materials, such as wood or bone. Details of all these methods, shown in italics, will be found elsewhere in this encyclopedia.

The *use of space* is fundamental to the understanding of human activity, and is recorded on a wide range of scales – at the level of a landscape, a settlement a cemetery, a house, a room, or a hearth. Much of field archaeology is taken up with measuring location, usually in three dimensions and archaeologists produce some of the most precise and

fastidious of all land surveys. The use of space is analyzed by *plotting* objects, and *planning* features and structures. Details of the use of space inside a building may also be determined by chemical and geophysical mapping (Carver 2011, Chap. 2). The many kinds of result include the determination of activities, routeways (paths, tracks), social hierarchies (from room and house size), and sequence (by comparing alignments).

On excavated sites, the *sequence* is worked out by stratigraphy – the order that contexts and features succeeded each other in the deposit. Their relationships (which came first, which came after) are recorded on site and drawn up in comprehensive *stratification diagrams*. Archaeologists also record sample sequences by cutting a slice through a deposit and drawing the set of layers seen from the side and shown in *section*. Sequence may also be informed by absolute dates of material in the assemblage and by relationships in space (see above). Spatial analysis also plays a role in determining sequence.

Sequence, space, and assemblage together produce the site model or site narrative – our best archaeological account of events that occurred at a place. There will be more research to come – placing these events alongside others near and far, and making better sense of them in human and historical and environmental terms. In this process, a vital ally is *ethnoarchaeology*, which provides analogies from ancient practice and behavior drawn from observations made in modern communities.

6. *PUBLICATION*. Drawing on the analyses, the results of fieldwork are modeled or synthesized, and are then distributed to the people who need them. *Through different kinds of publication* in the modern profession, the range of users is considerable. CRM archaeologists have to report their findings rapidly clearly and succinctly in Client Reports. Researchers will look to outlets in journals and monographs appropriate to the research community. The public are served by exhibitions and displays supported by popular summaries. And all the records made are deposited in an archive (often digital) for the long-term curation of information for the use of future generations.

Terrain

Procedures for survey and excavation are greatly varied the world over, since the character of archaeological sites, and what we want to know from them, both vary. The geology and topography of the land, and the way it has been treated by humans (quarried, cultivated, built on) has the collective term *terrain*. In general, the terrain is the greatest influence on the way archaeological information has been captured, and thus how it can be accessed and understood through investigation. Broad flat sites with little stratification in open country can be best examined in wide areas, and their rewards are to offer comprehensive plans of a settlement or cemetery, while deeply stacked strata under a modern town is much less accessible but offers excellent accounts of historical sequence using stratification. At each site, local events will have influenced the way that archaeological strata have built up and survived. Frost or flood may crack or disperse strata. Organic materials may decay, so that structures of wood become barely visible. A waterlogged site, on the other hand, preserves wood; but if the water flows, objects may migrate out of their original layers and be redeposited in much earlier (or later) contexts. These are *processes of site formation* which deserve to be studied both in general terms and site by site (Schiffer 1987; Goldberg and Macphail 2006).

A number of case studies are given in this encyclopaedia to illustrate different responses to different challenges the world over (see "Cross-References"). From England, we have an example of *landscape mapping* applied to a favorable terrain, using surface collection and geophysics deployed as far as possible to give total coverage. *Motorway construction* in Ireland gives an example where very comprehensive coverage was again achieved, both in survey and excavation, in advance of motorway construction. Stark contrasts in terrain are provided by the struggle to investigate *permafrost sites* in Siberia and sites embraced by *jungle* in Belize (Chan). Particular site types also provoke certain kinds of practice. *Klithi* (Greece) shows an exemplary approach to rockshelters in

the 1980s, while the *Pinnacle Point* cave site is deploying advanced methods of remote sensing. Three examples show how information can be won by careful excavation from sites where stratified layers are sparse: an *upper palaeolithic floor* in Switzerland, a *Lapita settlement* in the Mariana Islands (Pacific Ocean), and a Neolithic, *linearbandkeramik settlement* in Germany.

Specially revealing sites demanding particular approaches are the well-preserved wetland *crannog*, a type of artificial island in Scotland; the *tell*, a large mound created by the decay of a long sequence of mud-brick structures (the example is from Syria); and a *terp*, artificially raised settlement mounds in the Netherlands. An alluvial site in Italy Terramara and hillforts in the *Czech Republic* likewise require their own procedure. *Human burials* are rich sources of demographic information, and need to be dug with an enhanced care. A pioneering example of a *burial mound dissection* from central Sweden included the lifting of the entire burial chamber for study in the laboratory. A *mining site in Spain* and an *urban site in New York City* show something of the ingenuity required from excavators wishing to profit to the maximum from what terrain and opportunity offer.

An example of a project mainly dedicated to building recording is seen at *Bam* in Iran, where an archaeological team was faced with the challenge of recording of the buildings of a famous historic town severely destabilized by an earthquake. Our last example is of *ethnoarchaeology* in action: a record of the Gilund potters, themselves now under threat of economic extinction.

There is archaeology in every country and every country's archaeology is of equal value to the world as a whole. There is a world agenda, which seeks to understand the stories of every land and draw general conclusions from them, and there are local agendas in which the local heritage is paramount. These tensions between the values of scientific research and the values of cultural property result in different national strategies and attitudes toward the past. The values may change through time and sometimes look outward to international goals and sometimes inward to the national social mission. There are pioneers of field archaeology who have achieved some prominence but they are usually the instruments rather than the causes of particular forms of practice. For these reasons, rather than credit selected great figures with making all the advances, we have thought it more interesting to study the circumstances in which some of the more widespread *traditions* have developed: the American, Polish, British, Scandinavian, French, Australian, Chinese, and Japanese experience is considered in a number of brief contributions.

Field Schools, Archaeological

Roger Martlew
Yorkshire Dales Landscape Research Trust, Kettlewell, North Yorkshire, UK

Introduction

Although widely recognized as fundamental to the discipline, the provision of practical skills training in archaeology is currently a cause for concern, particularly in the UK, in response to continuing changes in the structure and funding of archaeological activity. A divergence has grown between training needs in the strong independent sector and the requirements of increasingly "professionalized" developer-funded units. In addition, a gulf has grown between field schools that provide training as part of an academic degree and the need for vocational training in support of a career in commercial archaeology (Aitchison 2004). Behind these issues lies a concern about the finite nature of archaeological evidence and the inevitably destructive nature of skills training "on the job." A rise in community archaeology projects funded through the Heritage Lottery Fund also represents a shift in emphasis which, despite the best intentions, has raised concerns about training needs in the light of an enthusiasm for invasive research (Thomas 2010). Despite these concerns, field schools continue to provide opportunities for people of all ages and abilities to acquire skills in the practice of archaeology and frequently also in their own personal development: the social aspects of field schools and their role in the development of the discipline as a whole should not be underestimated (Schofield 2011).

Definition

The term "Archaeological Field School" covers a wide variety of practical training opportunities, mostly but not exclusively associated with an educational institution. It may relate principally to an annual field course run by a university or college as part of an archaeology program, but in a few cases, field schools are run by independent organizations and are open to anyone who wishes to take part; assessment and accreditation are occasionally available, either through a formally recognized system or as ad hoc records of achievement.

Field schools provide training and experience in archaeological fieldwork skills, usually in the techniques of excavation, but also sometimes covering other practical skills such as topographical and geophysical survey, the recording of standing buildings and finds analysis. They are usually residential, and minimum periods of attendance may be specified. Costs can vary enormously

depending on the quality of the residential component (from "squatting" in borrowed buildings to camping, hostels, or study centers) and the degree of subsidy that might be available.

Key Issues/Current Debates/Future Directions/Examples

Field schools exist at one end of a spectrum in a discipline which has a very mixed approach to practical skills training. At the opposite end of this spectrum, excavation skills are picked up by default on projects where the overriding emphasis is on getting the job done. This need not be restricted to developer-funded projects, but the pressures of commercial archaeology are often perceived as running counter to any substantial training input. "Training excavations" exist somewhere in the middle of the range of training opportunities, with more or less priority being given to instruction while ensuring that progress overall is not unduly delayed. The majority of university-based undergraduate field experience falls into this category, with students working on excavations in support of the research goals of staff or postgraduates. The quality of training provided in these circumstances may be highly variable, with some excellent reports but also a less than satisfactory learning experience in some cases as reported in a recent survey (Croucher et al. 2008: 30).

Currently, there is little coherence to the provision of training in practical archaeological skills through field schools, despite the development of National Occupational Standards as a benchmark for vocational training by the Archaeology Training Forum (2007). University-based field schools are more likely to adhere to their own internal accreditation requirements, and with a general maximum period of 4–6 weeks spent on fieldwork training, this element is in practice a relatively minor component of a 3-year degree program (Everill and Nicholls 2011). Concerns within the HE sector focus on the impact of the introduction of tuition fees and students' abilities to support themselves financially, with previous years being presented as a "Golden Age" for fieldwork training (ibid. 8). Although most HE institutions provide some form of financial support, there are concerns about the ability of students in the future to meet the extra costs usually implicit in attending a Field School and the conflict with increasing pressures to obtain paid employment during the summer vacation or to uphold existing commitments to part-time employment.

Fieldwork training has, in the past, been the focus of some notable field schools or dedicated training excavations, and university extramural departments (more recently re-branded as continuing education) have made a major contribution. Among the most significant of the early training excavations were those run by Philip Barker at Wroxeter in the late 1970s/early 1980s for Birmingham University Extramural Department. These field courses have epitomized the spirit of university extramural teaching, being open to all and providing the highest quality of instruction. They have inevitably suffered as a consequence of changing patterns in university-based adult education, and the disappearance of this active support structure is of great concern (Lee 2009).

Other field schools in the UK have been run by organizations outside the formal education system; early examples include excavations at Bryn y Castell run by the Snowdonia National Park, at Strageath run by the Scottish Field School of Archaeology, and residential courses run at the Kindrogan Field Center. In many cases these have been inspired by the presence of individual archaeologists within these organizations, but recent economic trends have tended to curtail these opportunities significantly as the jobs supporting them have been cut back. In some cases, however, new training opportunities are being developed, for example, through the Dales Heritage Field School run by the Yorkshire Dales Landscape Research Trust (http://ydlrt.co.uk), which was created following the closure of the School of Continuing Education at the University of Leeds. The Kent Archaeological Field School (www.kafs.co.uk) is another independent organization which has now been offering a wide variety of training opportunities for 10 years.

A major strand which is increasingly taking up the role of providing "on-the-job" training and practical experience arises from the strong tradition in the UK of public or community archaeology, organized by local archaeological societies and more recently by community groups with funding

from the Heritage Lottery Fund. Some local society projects have been set up as field schools, and "learning" and "participation" are two key themes for HLF-funded projects. The training needs in these circumstances are many and varied – some archaeological societies have developed a wealth of in-house expertise which can be passed on to new members, while HLF funding supports the contracting-in of specialist expertise and "mentors." However, major concerns have been expressed with this type of project-specific funding (Thomas 2010), including the ability of groups to maintain activities in the long term and the lack of progression routes by which people can continue to develop their skills outside an increasingly expensive formal education system.

Practical experience in archaeological fieldwork skills can increasingly be acquired through field schools that recognize the widespread public interest in the past and are happy to welcome absolute beginners. Opportunities to suit a wide range of interests and pockets can be found through websites such as the directory of digs published by the popular magazine *Current Archaeology* (http://digs.archaeology.co.uk), the regular briefings published by the Council for British Archaeology (http://www.britarch.ac.uk), and on a worldwide basis through organizations such as the American Anthropological Association (http://www.aaanet.org/profdev/fieldschools/) or ShovelBums (http://www.shovelbums.org/index.php?option=com_sobi2&Itemid=100). All of these organizations provide directory listings and disclaimers about the actual experience and quality of training on offer: it remains to be seen whether field schools can build on current foundations to develop a more coherent approach towards training in the essential practical skills of archaeology.

Field Stabilization of Immovable Heritage

Thomas Roby
Getty Conservation Institute, Los Angeles, CA, USA

Introduction

In recent decades, conservation professionals have been increasingly involved in field excavations in order to stabilize materials during the critical moment when they are most susceptible to rapid and severe deterioration due to the radical change in the environment from buried to exposed

states. While it is more common for archaeological objects removed from a site to be subject to stabilization treatments during the excavation process, similar measures are now more frequently being planned and carried out in the field also on immovable heritage, namely, the architectural remains of a site, and the site itself, to prevent their deterioration or loss. Both preventive conservation measures and remedial interventions to stabilize sites during excavation, followed by monitoring and maintenance programs, are essential components of conservation and management planning for archaeological sites (Fig. 1).

Definition

In situ stabilization interventions, whether they are remedial treatments to correct damage or preventive measures to limit future deterioration and whether they are carried out during or long after the site's excavation, can encompass temporary or emergency measures, as well as complete and planned conservation programs. The variety of intervention options should be undertaken in the context of site-wide conservation and management planning and, on the basis of an assessment of condition, significance and degree of exposure (risk) of all site remains. Site assessments and conservation intervention planning involve professionals from different disciplines in addition to archaeology, such as architects, engineers, and conservators, as well as from allied fields such as soil science and hydrology. All stabilization interventions, whether they address deterioration at a structural level or on surfaces, should follow the conservation principles of documentation, reversibility, and minimum intervention to preserve the physical integrity and authenticity of sites. An effective and increasingly practiced preventive measure to stabilize sites and their excavated

Field Stabilization of Immovable Heritage, Fig. 1 Preventive measures to stabilize and protect sites: temporary seasonal covering to protect an excavated pavement (foreground), wall capping intervention to stabilize and protect wall tops, and a permanent shelter to protect decorative surfaces (background). (Photo: Livia Alberti, J. Paul Getty Trust)

remains is reburial. Yet it remains an option that is often considered as a last resort rather than an essential tool to preserve our archaeological heritage.

Key Issues/Current Debates/Future Directions/Examples

Reburial and Other Preventive Measures to Stabilize Sites

The creation of the professional journal "*Conservation and Management of Archaeological Sites*" (James and James, then Maney) in 1995 has played a significant role in drawing attention to site stabilization by greatly expanding the literature focused on conservation activities on archaeological sites. One of the journal issues has published the proceedings of an international colloquium on the reburial of archaeological sites (Stanley-Price and Burch 2004), an important preventive stabilization intervention option but a controversial one still among many archaeologists and national authorities. The introductory paper of the colloquium provides a general argument for the reburial of archaeological sites by examining the rationales for reburial, and the objections to it, while taking into consideration stakeholder, technical, and management needs (Demas 2004). Despite the convincing rationale and motivations for reburial, tourism, political pressures, and archaeological constituencies can still work against the conservation and management needs of a site, as one of the better-known case studies of site stabilization through reburial, the Laetoli Hominid Trackway site, revealed (Demas and Agnew 2006). In this case, the site is regrettably being pushed by the national authority to be uncovered and presented to the public, despite its remote location.

Without the institution of national policies to rebury sites or parts of sites, while presenting to the public those sites or parts thereof where the resources are available to protect and maintain them, more and more of our archaeological heritage will be lost (Caple 2000). Part of raising awareness about reburial as a conservation option is the need to document the positive results of reburial and to learn from the mistakes of past practice (Roby et al. 2010). Reburials have often been carried out in an ad hoc manner without sufficient planning and understanding of the type of new reburial environment to be created or the properties of the materials used, either fill materials or separation membranes. Lack of subsequent maintenance of reburials has also contributed to their poor performance in some cases. Yet experience has shown that when properly designed and executed (Fig. 2), the cost of maintenance of a site or site element is significantly reduced after

Field Stabilization of Immovable Heritage, Fig. 2 Preventive measures to stabilize and protect sites: an example of a reburial regime for an excavated pavement using a fill layer of sand, a separation membrane, and a covering layer of gravel to inhibit weed growth. (Photo: Thomas Roby, J. Paul Getty Trust)

reburial, which more than compensates for the initial cost of the reburial (Roby et al. 2014). A recent review of the literature on the reburial of mosaics in particular provides a summary of many of the issues pertinent to the reburial of sites in general (Roby and Demas 2012b).

In addition to reburial, there are a number of other preventive conservation measures that can be employed to stabilize sites and protect them from a variety of environmental causes of deterioration (Corfield 1996a; Stewart 2013).

Landscape stabilization measures, such as the installation of geogrids or nets, slope modification, and pinning, as well as revegetation can be used to prevent slope erosion, either soil or rock, and balk erosion.

Water management measures, such as dikes or diversion walls and drainage channels and pits, can be carried out to prevent damage from flooding and to evacuate water from sites when it accumulates. Shelters can also be constructed to prevent water erosion and flooding of elements of sites. In recent decades, shelters have been increasingly employed to mitigate the principal cause of deterioration of ancient monuments and excavated sites – water. They also provide shade which can create a more stable environment and at the same time can positively affect visitor comfort and site interpretation. However, if not designed in response to design criteria regarding the new sheltered environment, a shelter can adversely affect the conservation of a site. The causes of deterioration to the site that a shelter aimed to address can be exacerbated, and new unforeseen causes of deterioration can be created by shelters. For example, by concentrating rainwater at the perimeter of a shelter, erosion and salt crystallization phenomena can be worsened by a shelter if not designed with adequate drainage measures.

If shelters are to perform their primary purpose of protection, the architect designing a shelter needs to work with other disciplines and conservation professionals and be provided with and respond to a conservation brief with specific performance criteria coming from an assessment of the site and collection of local environmental data (Demas 2001; Stanley-Price and Matero 2001; Roby and Demas 2012a).

In addition, other preventive measures, such as regular maintenance and revegetation, can be employed to control vegetation and prevent site damage from plant and tree root growth.

Limiting access by animals, whether they burrow, graze, or roost, such as by exclusionary fencing or netting or by altering their habitat, can also prevent damage to sites.

Remedial Interventions to Stabilize Sites

Although preventive conservation measures should be considered first in any site conservation and management planning before, during, and after the excavation process, remedial interventions also play a major role in stabilizing sites. These interventions should be limited to the minimum required to re-establish structural integrity of the site or site element.

Another key conservation principle to follow in planning site stabilization interventions is the use of appropriate, compatible materials which are also capable of being removed at a later date without causing damage to the original material.

In the past, inexpensive modern materials, such as reinforced concrete and cement, have often been used to stabilize site elements, which over time have led to accelerating deterioration of the adjacent original material, due to their very different physical/chemical and mechanical properties. The original materials should be identified and their basic properties assessed in order to identify the most compatible repair material, which in general will be as similar to the original material as possible, whether the site elements are constructed of masonry bonded with lime or gypsum mortars or of earthen materials.

Prior to undertaking any stabilization interventions, recording should be carried out to document both the condition of the site or site element and the interventions themselves. This recording will be critical to effective monitoring and maintenance in the future (Corfield 2003).

Interventions can be grouped by those carried out to stabilize the structure of an element and those to stabilize the surface. Structural interventions on site elements, which generally consist of masonry structures but also rock-cut or earthen materials, include filling of areas of loss with

Field Stabilization of Immovable Heritage, Fig. 3 Remedial interventions to stabilize sites: structural repair of an architectural element using multiple carbon fiber strapping around the architrave blocks and a tie beam inserted above them. (Photo: Livia Alberti, J. Paul Getty Trust)

like material; grouting of deep voids and fractures with mortar; insertion of structural pins, ties, or bolts, or the use of strapping, to keep elements together (Fig. 3); and application of a layer of mortar or earth as a protective capping for wall tops.

Stabilization of surfaces, sometimes of a decorative nature, carved stone, stucco, wall painting, and mosaics, to mention a few, includes filling of areas of loss with like material, micro-grouting of voids behind the surface (Fig. 4), and mortar edging repairs to contain and protect areas adjacent to loss. Friable surfaces can also be stabilized with the application of consolidant materials, often synthetic in nature, both inorganic and organic. Consolidation treatments will change the properties of the treated material and will generally not be reversible and will affect the retreatment of materials, so such treatments should be undertaken by professionally trained conservators or specially trained architects (Stewart 2013).

In principle, remedial interventions should employ materials that are reversible, namely, that can be removed at a later date without causing damage to the original material. For this reason, and also due to their compatibility with most ancient porous building materials, lime- or earth-based mortars are generally preferred for most

Field Stabilization of Immovable Heritage, Fig. 4 Remedial interventions to stabilize sites: stabilization of a mosaic surface through grouting with lime-based liquid mortar. (Photo: Sebastiaan Godts, J. Paul Getty Trust)

treatments of architectural elements. For certain structural repairs, however, drilling into a material for the insertion of reinforcement elements, like pins, may be needed, as well as structural adhesives which are generally not reversible (Ashurst 2007). In such cases, intervention layers of a reversible material or adhesive may be applied between the original material and irreversible material to make the operation less irreversible.

Cleaning is an operation which is generally carried out before stabilization interventions in order to insure a successful treatment, as soil or dust present on or below surfaces will prevent the proper adhesion of mortars or other repair materials. Otherwise, cleaning with the aim simply of making the surfaces more visible should be avoided unless the presence of an accretion or film is helping to provoke the deterioration of the surface.

Levels of Intervention

Whether preventive or remedial, there are basically three levels of intervention that can be undertaken. First-aid or emergency treatments represent the first level, which aim to quickly prevent loss or collapse of site or architectural elements until sufficient time and funding are available to plan and implement a more complete conservation program for their long-term stabilization. For preventive measures, such interventions include temporary reburial or sheltering, while for remedial interventions, first-aid treatments could consist of shoring or propping of structures or balks. Regarding decorative surfaces of structures on site, facing with a tissue or fabric and a reversible adhesive or protecting broken edges from loss with mortar edging repairs can be considered part of this first level of intervention.

While publications exist which address this level of intervention for archaeological objects or movable heritage (see the entry on ▶ Field Stabilization of Movable Heritage in this encyclopedia), there are no similar texts addressing emergency treatments of immovable heritage. However, there are articles in the conservation literature which report on emergency treatments carried out during excavations, demonstrating that increasingly conservation professionals are present during excavation, not only those with training in objects conservation but also those with training in architectural and site conservation.

The second level of intervention is complete conservation treatment, which ideally should be based on a thorough condition assessment of the site, including both the characterization of constituent materials and their properties and the identification of prevailing causes of deterioration. An example of a preventive measure at this level of intervention would be the installation of new drainage systems for rainwater at a site or the cleaning of the ancient drainage system to make it functional again. The various remedial stabilization treatments mentioned above, both structural and superficial ones, are considered part of the conservation process and should be carried out in a management framework to stabilize and protect the site and its elements.

The third level is restoration or reconstruction, which aims to go beyond the minimum intervention required to stabilize the element and instead to add new material to the original in order to complete the element and render it more understandable to the visitor. This level of intervention has frequently been carried out in the past on archaeological sites. Some would argue that, if the interventions of restoration or reconstruction are well-documented to international standards, and therefore what is not original material is recognizable in the future by consulting the documentation, these types of intervention should be acceptable. However, this level of intervention is not consistent with recent and current international conservation charters and guidelines because it compromises the authenticity of the site or element (Jokilehto 2006) and can provoke damage to the original material over time.

Maintenance and Monitoring

All stabilization interventions, particularly those carried out in uncontrolled environments on sites, require monitoring of condition followed by maintenance operations as needed in order for the interventions to continue to be effective. Depending on the aggressive nature of the environment and the fragile nature of the site or its elements, the frequency of condition inspections will vary. Maintenance operations can consist of

vegetation removal, repair of previous stabilization interventions, repair of new areas of damage or loss, and repair of protection interventions such as shelters, reburials, or barriers. These operations require trained if not professional personnel and a consistently applied methodology of documentation of both inspections and interventions in order to determine the required interval of maintenance cycles to avoid future deterioration. An example of such a methodology has been developed recently for the training of technician-level personnel for the maintenance of mosaics on archaeological sites (Alberti et al. 2013) (Fig. 5), but the methodology could be adapted and applied for the maintenance of a variety of site elements to ensure that they are regularly and sufficiently inspected and kept in stable condition.

Field Stabilization of Immovable Heritage, Fig. 5 Maintenance and monitoring: documented regular inspections followed by remedial repairs with compatible lime-based mortars, as needed, will keep excavated site remains in stable condition. (Photo: Elsa Bourguignon, J. Paul Getty Trust)

Field Stabilization of Movable Heritage

Emily Williams
The Colonial Williamsburg Foundation, Williamsburg, VA, USA

Introduction

The conservation of sites and artifacts is an integral and important part of the archaeological process. Conservation has a role to play in the elucidation of the site and of the material recovered from it, and the process often starts with field stabilization and even before that with the planning process.

Definition

Field stabilization (also often referred to as "first aid for finds") aims to prevent objects from deteriorating both chemically and physically by using correct lifting, recovering, packaging, transportation, and storage procedures. Not all objects require intensive conservation treatment in a lab-based setting, but all objects require field stabilization.

Key Issues/Future Directions

During burial, objects are prone to biological, chemical, and physical decay. They are affected by a number of environmental factors including the following: the presence of water and oxygen, the degree of acidity or alkalinity, the temperature and redox potential (oxidative or reductive power of the environment), the depth of the soil overburden, the presence or absence of salts, their proximity to other objects and the materials from which those objects are made, and the condition of the object before it was buried. Organic materials, for example, may totally disappear in damp aerated soils but survive beautifully in anaerobic conditions (such as waterlogged deposits), in very dry conditions (such as the Southwestern United States or the Near East), and in close proximity to certain metals and their alloys (due to the toxicity of these materials to many microorganisms) (Chen et al. 1998). Unfortunately, the physical and chemical integrity of an object can be severely affected, while the object itself continues to look much the same. An example of this is waterlogged wood. The cellulose and hemicellulose in the wood are easily lost, leaving behind a fragile lattice of lignin that can collapse on drying, resulting in dramatic dimensional changes unless something is done to stabilize the wood. Another example are metal artifacts where salts absorbed during burial can contribute to the rapid corrosion of the metal once it is excavated.

Most objects deteriorate rapidly when they are first buried. Those that survive do so because they reach equilibrium with the burial environment; their deterioration progresses to a certain point and then either stops or drastically slows to a more sustainable rate. Once these artifacts are excavated, they are subjected to a new environment, which may be radically different from the burial environment, and they begin to deteriorate again unless a new equilibrium can be reached. The goal of field stabilization therefore is to move the object to a new state of equilibrium. This can be achieved by recreating aspects of the burial environment, for example, keeping waterlogged materials wet. Or it may be achieved by creating an entirely new environment, for example, using materials such as the Escal film® and the Revolutionary Preservation System®, to create very dry, oxygen-free environments aimed at preventing iron from corroding further, prior to more interventive forms of treatment (Mathias et al. 2004).

Occasionally objects cannot be removed from the ground safely without the application of an external support. This may be necessary because of the size of an object and the condition of the piece or to maintain the associations between multiple related components until there is more opportunity to understand them. Support may take the form of a consolidant that is applied directly to the object to help strengthen it internally, or it may take the form of an external support such as plaster bandages, steel lifting frames, or even freezing the object and the soil around it and lifting it as a block. The term "lifting" is most frequently used to denote a situation where an object is removed from its context after a support has been added.

There are several important points to consider prior to lifting any object. Lifting is a temporary stabilization technique that mandates future work on an object in order for it to be studied, exhibited, and understood. It is important to be clear as to why the object is being lifted and what will happen to it afterward. Museum storage units are littered with objects that have been lifted but never excavated or worked on further, either because interest or funding evaporated. It is best to have a plan in place that includes who will do the post-lift work, when the work will occur, what the end goals of the work are, and how it will be funded. If this is not in place and it is at all possible, it is better to rebury the object and return to it once suitable arrangements have been made. If the decision is made to lift an object, it is important to remember that excavation conditions are seldom ideal. In the field, it is rarely possible to get an object clean enough for study or exhibit. Further work will be needed to clean the object, provide permanent support for it, and stabilize it for the long term. The consolidants or supports applied in the field may need to be removed during this process and new ones applied. It is important to think about the reversibility (or removability) of the materials being used. Some materials are easily removed, while others, such as epoxy resins, can rarely be removed successfully. It should be noted that even when a consolidant is reversed, small amounts are almost always left behind, often in cracks or pores. These trace remnants can affect later analysis, so if analysis is planned, it is best to sample the piece before any consolidation is undertaken.

Documentation is an important part of the field stabilization process, and there are a number of forms it can take, including but not limited to written documentation, photography, and three-dimensional scans. It is important to document the actions taken and the materials used as thoroughly as possible, as they can impact both future treatment and analysis. It is much easier and less time-consuming for a conservator to reverse a consolidant if she/he knows what it is and does not have to test all the possible materials it could be. Similarly, a scientist wishing to analyze certain materials may be able to use an object's treatment history to determine which objects are suitable (or not) for analysis. For these reasons, conservation documentation should be integrated into the main excavation archive. Additionally, if field stabilization or later conservation has occurred, it should be noted and summarized in the overall project publication.

Planning is a key component of any form of field stabilization. There are three models that are often adopted for the involvement of conservation on a site. The first is to have the conservator working on the site full time; the second is to have a conservator on call who can visit the site frequently and help stabilize fragile materials, and the third is to have a member of the team who oversees the welfare of the finds with advice from a conservator. In this last scenario, the conservator may only visit the site for emergencies and complex conservation problems, or if the site is remote, all stabilization activities may be carried out by a member of the excavation staff. The choice of which level of involvement is appropriate for the site should, ideally, be made in conjunction with a conservator and should consider factors beyond the mere budget implications of each scenario; for example, thought should be given to what sort of artifacts are likely to be recovered, the conditions they are likely to be recovered from, the size of the excavation, whether a conservation lab is available near the site, and what the conservation capacity of the receiving institution or museum is. The more thought is given to these matters up front, the more successful the outcomes are likely to be. Field situations are unusual – no site ever presents the same exact problems as another site – and stabilization activities can be hampered

by additional constraints, such as weather and the availability of products or materials.

In some ways, field stabilization is one of the more conservative aspects of archaeological conservation, a fact which is reflected in the literature on the topic. This is due in part to the variables in sites, artifact materials and condition, and the availability of stabilization materials; what worked beautifully in one location may be less successful at another site or difficult to replicate. Additionally, field stabilization labs are often quite basic, and few are furnished with the equipment necessary to scientifically test new materials, a prerequisite for publishing in most conservation journals. As a result, many of the newest developments in the field are focusing on documentation techniques, particularly 3D scanning (Karas et al. 2010; Logan et al. 2010) and the application of 3D computed tomography to visualize archaeological objects in blocks of soil (Stelzner et al. 2010). This is a trend that is likely to continue as these imaging techniques become more powerful and more affordable.

Basic Species Information

Ficus carica, fig, common fig. The fig tree has a short, branched trunk, which creates a broad crown with rather large and usually emarginated,

deciduous leaves. Its life span is short (decades) in comparison to that of an olive tree. The fig protects itself against ruminants by producing bitter latex found in its leaves and young branches. It is dioecious, i.e., the species produces male and female trees.

The flowers are tiny, grouped by the hundreds in a closed inflorescence called a syconium, which develops into a fruit of almost spherical to pear shape, with a somewhat rounded apex and a narrow base. An opening, called ostiole, is located at the center of the fig's apex (Fig. 1). Pollination is carried out by a tiny wasp (*Blastophaga psenes*) that develops inside the male syconium, which is dry, is spongy, and has uncomfortable taste. The wasp, which lives in symbiosis with the fig, exits the male syconium and flies to find a female tree; it then penetrates through the ostiole of the female syconium. When ripe, the 3–7 cm long fruit contains up to 1,000 fertile nutlets, each with a diameter of approximately 1 mm and containing a single seed (Fig. 2). Because the fig is fleshy and sweet, it attracts birds and bats, which eat them and disseminate the seeds, the natural reproduction scenario of this species.

The fig is one of the major traditional fruit-bearing trees in the Mediterranean and Middle Eastern regions. In countries surrounding the Mediterranean Sea, wild fig distribution largely overlaps that of the grapevine and olive (Zohary et al. 2012).

Figs: Origins and Development, Fig. 1 Ripe fruits of a common fig variety, Brown Turkey. (Photo by Dr. O. Simchoni)

The fig has been grown for many thousands of years for fresh as well as dried fruits. In ancient records, including the Bible, there are numerous references to the fig being eaten and grown by humans. In fact, one opinion in Jewish tradition claims that the Tree of Knowledge was the fig and not the apple, a fact derived from Adam and Eve's sewing fig leaves together to cover them following their eating of the Tree (Condit 1947; Flaishman et al. 2008).

It was generally accepted that horticulture started much later than grain crop agriculture, because cereals and pulses are "short investment" annual crops, while fruit trees are perennials and begin bearing fruit some years after planting. However, recent archaeological findings have pushed back fig horticulture by several thousand years. Charred fig nutlets and fruit fragments were retrieved from some early sites in southwest Asia, such as the Pre-Pottery Neolithic A (PPNA) sites Gilgal and Netiv Hagdud, Lower Jordan Valley,

Figs: Origins and Development, Fig. 2 Half fleshy fig showing the nutlets. (Photo by Dr. O. Simchoni)

Israel, dated to the 12–11th millennia BP (Fig. 3). Fig trees may therefore have been the first domesticated plant of the Neolithic revolution, which preceded cereal domestication by about a thousand years (Kislev 1997; Kislev et al. 2006a, b).

It is suggested that the first step of domestication was unintentional (later intentional) planting of branches of a selected female fig in the mother-tree habitat. Indeed, vegetative propagation by Neolithic people was the first step of domestication, because it preserved exactly the qualities of the mother plant. Apparently, the Neolithic gardener discovered that a fig branch driven into the ground would root and start to grow. The second step was an expansion of the female fig orchard to additional fields and eradication of unwanted female figs and other trees to make room for the preferred females. The third step was the residents noting parthenocarpic mutations in their fig trees. These novel fig plants produced fruits without wasp fertilization and had a much longer fruiting season than their non-parthenocarpic varieties. They were then chosen for vegetative propagation. Since these female trees were independent of the presence of male figs, they were ready for expansion to new regions where figs did not grow naturally.

The fig crop would be extremely valuable to Neolithic farmers, who, upon occasion, had no winter reserves of wild cereals and pulses. This could occur if the seeds were eaten throughout the summer and all the rest had to be sowed at the beginning of winter for the next year's crop. However, by planting a fig branch in the ground for receiving a fruit tree in the near future, even after a few years, they took nothing away from their dietary reserves.

The fruit ripening is not uniform and a small number of figs ripen every day. The inhabitants could have enjoyed fresh or dry sweet figs throughout the year, and they seem to have even grown them near their homes. The fig was relatively more important during Neolithic and Chalcolithic periods, because grapevine and olive were mainly cultivated for fruits and not for their liquid products – wine and oil. This lack of production may have resulted from the lack of suitable vessels for large-scale production (Garfinkel 1999).

Figueiredo, Silvério

Silvério M. D. Figueiredo
Quaternary and Prehistory Group, Geosciences Centre, Coimbra, Portugal
Instituto Politécnico de Tomar, Tomar, Portugal
Centro Português de Geo-história e Pré-História, Tomar, Portugal

Basic Biographical Information

Silvério Manuel Domingues Figueiredo (Fig. 1) is a Portuguese archaeologist. He grew up in Lisbon and graduated in history from Universidade Lusíada in Lisbon in 1994. In 1995, Figueiredo studied paleontology made, as an external student, with the Faculdade de Ciências, Universidade de Lisboa. He was awarded a Ph.D. in prehistory archaeology from Universidad de Salamanca in 2010, on the basis of his research into Pleistocene birds in their paleontological and archaeological contexts.

Figueiredo, Silvério, Fig. 1 Silvério Manuel Domingues Figueiredo. (Photography by Edmundo Rijo)

In 1993 Figueiredo established, with some colleagues, the Centro Português de Geo-História e Pré-História, a research association in paleontology and prehistoric archaeology. Since 1991 he has participated in and directed several archaeological excavations. In 2000 he began teaching at the Instituto Politécnico de Tomar in the areas of archaeology, paleontology, and history. In 2009 he established the Laboratório de Arqueozoologia e Paleontologia at the Instituto Politécnico de Tomar and Centro Português de Geo-História e Pré-História.

Major Accomplishments

Silvério Figueiredo has been dedicated to archaeology since 1991. He participated in the excavations of several important Middle Paleolithic sites in Portugal, such as Foz do Enxarrique, Conceição and Casal do Monte. Since 1996 he has organized, within the framework of Centro Português de Geo-História e Pré-História, various congresses, seminars, and lectures on paleontology and archaeology. He has conducted lectures and participated in national and international congresses on paleontology and archaeology. Between 1996 and 2000 Figueiredo worked in the Geological Museum of Lisbon, making an inventory of paleontological and archaeological collections, and between 2000 and 2002 he worked at the National Museum of Archaeology, participating in the inventory of collections of prehistoric archaeology.

Figueiredo has directed research projects in archaeology and paleontology in the region of Espichel, south of Lisbon, since 1998. Between 2000 and 2005, he coordinated research for the development of the "Archaeological Chart of Montijo." He is connected to Instituto Politécnico de Tomar (Tomar), Centro Português de Geo-História e Pré-História (Lisboa and Golegã), Laboratório de Arqueozoologia e Paleontologia (Tomar), Instituto Terra e Memória (Mação), and Centro de Geociências da Universidade de Coimbra (Coimbra).

Film, Archaeology in

Peter Hiscock
Department of Archaeology, University of Sydney, Sydney, NSW, Australia

Cinematic depictions of archaeology and archaeologists in film are diverse. Genre classifications are crude expressions of thematic difference in movies, with multiple genres often being hybridized in a single film, but they are one way to characterize the variety of films containing archaeology. The most common genres in recent years have been action/adventure, horror, and science fiction. But it was in westerns that archaeologists were first commonly screened. During the 1930s, archaeologists featured in westerns such *Hidden Valley* (1932), *Riders of the Whistling Skull* (1937), *Death rides the Range* (1939), and *The Fighting Renegade* (1939). Such early films often portrayed archaeologists as pith-helmeted intellectuals who were elderly and neither streetwise nor athletic. To drive the narrative action forward, these archaeologists were paired with the lead action figure, archetypically male, young, and sporty. Plots usually had the archaeologist hiring a cowboy to guide them or rescue kidnapped members of the scientific team. As narrative sidekick the archaeologists were often wounded or killed, but sometimes the aged archaeologist also fought the bad-guys and sometimes archaeologists were the bad-guys. Virtually the same plots were found in popular science fiction serials of the 1930s, such as *The Lost City* (1935) *The Phantom Empire* (1935), *Ace Drummond* (1936), and *Undersea Kingdom* (1936), and this is not surprisingly because those early science fiction narratives were effectively westerns set in exotic contexts with high technology. As cinematic science fiction developed archaeologists and archaeological themes continue to be occasionally represented (e.g., *Forbidden planet* 1956; *Planet of the Apes* 1968; *Alien* 1979; Stargate 1994; Prometheus 2012).

Depictions of archaeologists in modern cinema grew out of the action of early westerns, and the influence is still potent and obvious. The costume of Indiana Jones, his hat, jacket, and gun all hark back to these Western images, and his code of behavior is largely that of Tucson Smith (note the name) in *Riders of the Whistling Skull* (1937) or Bob Harding in *Hidden Valley* (1932). A key change in representations since early cinema is that the characters of action hero and knowledgeable archaeologist have morphed into the modern filmic persona of adventurous archaeologist exemplified by Indiana Jones.

Archaeological work and the nature of the ancient human past were variously sketched in the early decades of cinema. Depictions of life in

the Stone Age began in silent films, with *The Cave Man* (1912), Chaplin's *His Prehistoric Past* (1914), *The Stone Age* (1917), and Keaton's *The Three Ages* (1923). These movies employed comic situations to provide commentary on human nature and modern life. "Caveman" films have persisted ever since, often with the same comic role, as in *Caveman* (1981) or *Year One* (2009). Dramas of Palaeolithic people have also been attempted: set in the past such as *One Million Years B.C.* (1966), *La guerre du feu* (*Quest for Fire* 1981) and *10,000 BC* (2008) or in the present such as *Iceman* (1984).

Historical dramas dealing with classical civilizations have also been persistent over the past century, as in Griffith's *Intolerance: Love's Struggle Throughout the Ages* (1916), *Ben-Hur* (1959), *Spartacus* (1960), *Cleopatra* (1963), *Gladiator* (2000), or *Troy* (2004). Such films typically explored the epic narratives of history and in many ways were not attempting to be historically accurate.

In films depicting the past, however, it is the image of archaeology as the pursuit of lost civilizations and their treasures which was often repeated. Hollywood focused on this theme from the 1930s onwards, commencing with films such as *The Live Wire* (1935) and *King Solomon's Mines* (1937, remade 1950, 1985), a trend encouraged by parallel themes in *Lost Horizon* (1937, remade 1973). The tradition of combining adventure with archaeologists searching for lost civilizations and treasures has continued in a stream of B-movies until today, such as *The White Orchid* (1954), *The Mole People* (1956), *The Lone Ranger and the Lost City of Gold* (1958), *Invaders of the Lost Gold* (1982), *The Lost Treasure of the Grand Canyon* (2008), and *Lost Treasure of the Maya* (2008). Additionally archaeology is now commonly used as a backstory for action/science fiction movies dealing with ancient civilizations, as exemplified by *Doom* (2005) or *Timeline* (2003).

A number of films also explored human relationships in the physically extreme and dangerous situations archaeological adventurers are thought to inhabit. Films such as *Bitter Victory* (1957), *Legend of the Lost* (1957), *March or Die* (1977), or *The English Patient* (1996) are classic examples, but movies have also explored the dangers and difficulties of relationships with family or friends as in *The Purple Rose of Cairo* (1985), *Old Explorers* (1990), and *Around the Bend* (2004), or even of sexual encounters in the soft-core erotica of *Laura's Toys* (1975).

Cinematic archaeologists have typically been white and male, but even in Hollywood these stereotypes have sometimes been broken. In the 1930s and 1940s, a series of movies depicted Asian archaeologists acting as detectives, or detectives acting as archaeologists, such as *Charlie Chan in Egypt* (1935), *Mr. Moto Takes a Vacation* (1939), or *Phantom of Chinatown* (1940). Female leads have been rare, but notable examples include *Lara Croft: Tomb Raider* (2001) and its sequel *Lara Croft Tomb Raider: The Cradle of Life* (2003), as well as the telemovie *The Last Templar* (2009). More frequently female archaeologists are presented as only minor characters, often with the implication that it is a quirky social role for a woman, as in *Tea with Mussolini* (1999). Even more rarely has Hollywood selected African American actors in films with archaeological themes, but it has occurred in movies such as *Blood Tide* (1982). When indigenous people have been included in films, they are often represented as being betrayed and exploited by archaeologists. In films such as *Raiders of the Lost Ark* (1981) or *A Thief of Time* (2004), archaeologists are presented as obsessively searching for treasure or knowledge with little concern for the consequences for native peoples.

Fundamental elements of filmic representations of archaeologists, archaeological practice, and the ancient human past were shaped in the early 1930s, particularly through the powerful work of Boris Karloff in *The Mummy* (1932) and *The Ghoul* (1933). Building on Egyptian/mummy themes in earlier silent films (Lant 1992), these movies presented narratives in which popular concepts of reanimation and resurrection were evoked, and their dramatic impact and popular appeal linked plots about archaeology with supernatural processes. This articulation has been repeated and reworked until it became the central theme in archaeological films. Movies reworking *The Mummy*, in which archaeologists accidently reanimate mummies and/or battle the monstrous beings, have persistently been released: from Universal Studios (e.g., *The Mummy's Curse* 1944; *The*

Mummy's Ghost 1944; *The Mummy* 1999; *The Mummy Returns* 2001, *The Mummy* 2017), from Hammer Productions (e.g., *The Mummy* 1959; *The Mummy's Shroud* 1967) and by numerous small studios and independent film makers. These plots were parodied in films such as *Abbott and Costello Meet the Mummy* (1955), *Where's My Mummy?* (2005), and *Bubba Ho-Tep* (2002). Non-Anglophone cinemas have played with the notion, as in *La momia azteca* (*The Aztec Mummy* 1957) and its sequels from Mexico, *Belphégor - Le fantôme du Louvre* (2001) from France or *La malédiction de Belphégor* (1967) from Italy. Variations on the theme were also presented in films exploring spiritual possession by ancient entities in films such as *The Awakening* (1980) and *The Exorcist* (1973).

Ever since *The Mummy* the connection of archaeology and the supernatural has been the strongest narrative theme in films dealing with the discipline. This connection was transferred to movies without a reanimation element but with supernatural, or trans-natural, events and evil forces threatening us, and opposed/fought by archaeologists. This was the basis for horror films such as *The Exorcist* (1973) and its prequels, *The Lair of the White Worm* (1988) and others. Supernatural themes are also seen in plots in which extra-terrestrial events threaten humanity or in which the use of objects left by aliens or gods are about to be used to destroy humanity. Examples of these films include *Lara Croft: tomb raider* (2001) and *Lara Croft Tomb Raider: The Cradle of Life* (2003), *Stargate* (1994), *Stonehenge Apocalypse* (2010), *A genesis found* (2010), and of course the iconic archaeology movie *Raiders of the Lost Ark* (1981). In those narratives, archaeological sites and archaeological knowledge are central to saving the situation. Increasingly such Hollywood plots have become entwined with the pseudo-scientific narratives of alien astronauts shaping the human past, as directors such as Roland Emmerich (*Stargate* 1994), Steven Spielberg (*Indiana Jones and the Kingdom of the Crystal Skull*, 2008), Ridley Scott (*Prometheus*, 2012) have all explored the ideas of Erich von Däniken.

Emphasis on supernatural and extra-terrestrial events in archaeological movies reflects the reality that cinema explores the interests of the public rather than the nature of archaeological practices or discoveries (Hall 2004; Noble 2007; Hiscock 2012). Often the narratives presented in films are founded on popular religious and nonscientific beliefs, and cinema has commonly presented archaeologists either as meddling academic elites who release danger into the world through their ignorant actions or as advocates for pseudo-archaeological views (Hall 2004; Hiscock 2009, 2012). Representations of archaeology in cinema can be viewed as a public dialogue about the nature of the past, the nature of contemporary culture, and the value of science. Movies have not so much romanticized or fetishized archaeology as they have employed nonspecialist fictions of what it is to be an archaeologist to pursue mythic imperatives.

Finch, Jonathan

Alasdair Brooks
The Grand Egyptian Museum (GEM) Project, Hill International, Giza, Egypt

Basic Biographical Information

Jonathan Finch, an expert in designed and agrarian historic landscapes of the postmedieval period, began his academic career at the University of East Anglia, completing his M.A. in Local and Regional History (1989) and his Ph.D. (1997) at the latter

institution. He was briefly a part-time lecturer at UAE (1997–1998) before taking up a 1-year post in the Department of History and Archaeology at the University of Wales, Bangor (1998–1999). He was then appointed lecturer in the Department of Archaeology at the University of York in 1999; he is currently a reader in the same department and is also Director of Studies for York's MA in Historical Archaeology program. He was elected a fellow of the Society of Antiquaries of London in 2006.

Major Accomplishments

Though Finch's recent focus has been on post-medieval landscapes, his initial research interests were more oriented toward commemoration in both the medieval and postmedieval periods. Changes in the iconography of commemoration before 1400, the impact of the Reformation on commemoration, and the role of commemoration in constructions of social identity have all been strong themes in this work (Finch 2000, 2003, 2007a). This continues to be a research interest for Finch, who is currently working on a thematic summary of death, memory, and identity in Britain between AD 1000 and 1850.

Finch's research turned more directly toward postmedieval estate landscapes in the first decade of the twenty-first century. His work has a range of subjects related to the character, context, and development of landed estates (e.g., Finch 2004; Finch and Giles 2007). Yorkshire has been a particular geographical focus (Finch 2007b, 2008), and Finch has worked closely with the Yorkshire Country House Partnership – a joint venture between the University of York and seven country seats in the county – to develop new archaeological approaches to the archaeology of the eighteenth- and nineteenth-century estate landscapes. Some of this work was presented in the "Work and Play" exhibit hosted by Burton Constable, Brodsworth, Harewood, and Temple Newsam houses.

Finch built on the international connections of these estates to engage in international comparative research focused on the Lascelles family holdings in Yorkshire and Barbados. Finch's ongoing program of research at Harewood House (near Leeds) and its predecessor Gawthorpe Hall focuses on the seat of the Earls of Harewood, a title originally created for George Lascelles in 1812. The Lascelles family wealth had been made in the Caribbean – primarily Barbados – via sugar plantations, the slave trade, and the collection of local customs duties; as a result, in addition to Harewood House, they maintained extensive landed estates in the Caribbean, where Finch has also been directing fieldwork. His current research therefore uses the international Lascelles holdings to explore the global connections of rural landscapes by examining the relationships between both colonial and domestic environments while also studying the impact of West Indies land holdings on the English rural landscape (Finch 2017, 2019).

Recently, Finch has also turned his attention to the twentieth-century marginalized communities in rural landscapes, with a particular focus on a Heritage Lottery-funded project at the First World War site of Breary Banks, Yorkshire, which was home to both navvies (volunteer recruits) and German prisoners of war during its brief occupation.

Finger Millet: Origins and Development

Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Finger millet is the common English name of the crop *Eleusine coracana* (L.) Gaertn., a domesticated cereal of African origin which spreads in prehistory to Asia, also sometimes referred to as korakan or ragi (a widespread local name in India) or dagusa (in Ethiopia). Its English common name comes from the growth form of its seed heads (panicles) which take the form of several fingers (Fig. 1). This cereal is widely cultivated in eastern and central Africa, India, and Sri Lanka and extends eastwards through the Himalayas to southern China, the hills of Southeast Asia and into the hills of Taiwan, and parts of Indonesia and Guam. In Asia it is frequently a cereal in shifting cultivation systems, although it is also produced in permanent field systems on the plains of India.

Finger Millet: Origins and Development, Fig. 1 Photograph of finger millet panicle, in cultivation in the Western Ghats, Maharashtra, and India

It is also cultivated to a limited extent in modern Yemen and Oman. Although the wild progenitor species (*Eleusine africana* Kennedy-O'Byrne) is well established, where and how many times within the African native range of this species it was cultivated initially remains unclear (Hilu and De Wet 1976). Ecologically it is regarded as coming from an upland environment, and as a crop it is most commonly grown in hill zones, above 900 m. Nevertheless, it can be grown in the lowlands, to a limited extent in Africa and to a larger extent in India. In Asia upland races, which are especially widespread in the Himalayas from India to Nepal and southern China, appear to be a secondary adaptation. One limited genetic study suggested that the hills of western Tanzania might be the region of origin (Hilu 1995), while many botanists have pointed to the Ethiopia highlands as a point of origin (e.g., De Wet 2000). There remains no clear evidence from botany or archaeology on where within the range of the wild progenitor it was first brought into cultivation or whether this occurred more than once (Fig. 2).

Major Domestication Traits

Finger millet is somewhat less hardy than other millets, preferring richer and wetter soils, but it has exceptional storage advantages. Finger millet grains are rarely attacked by pests or spoil in storage, and

Finger Millet: Origins and Development, Fig. 2 Map of wild progenitor (after Hilu and De Wet 1976) and approximate limits of cultivation in Africa (after Murdock 1960) together with distribution of archaeological reports in Africa. (Based on the database of Giblin and Fuller 2011)

shelf life of up to a decade is commonly reported. Although it may survive with 500 mm of rainfall, it is generally grown on 800–1,000 mm. It is often the first crop in rotations of shifting cultivation or the second crop after rice, as it does not do as well on impoverished soils as other millets. While it can be made into porridges and flat breads, finger millet beers are traditional both in parts of Africa and Asia.

Studies of the crop processing of finger millet have been carried out in both Africa and India and indicate that it is a free-threshing grain, with most grains freely separated from chaff after one stage of threshing and winnowing. This may bias against preservation of this species by comparison to cereals, such as rice and most small millets, that require intensive dehusking (Reddy 1997; Young 1999).

Recognition of grains of finger millet should be straightforward if preservation is good (Fig. 3). It has a distinctive globose but angular shape, a short embryo, and a hilum placed at the edge of the embryo on a separate edge rather than on the ventral grain surface. The surface of the grain is distinctly sculptured with small warts. Nevertheless, there have been recurrent misattributions of other small millets to "finger millet" in older archaeological

Finger Millet: Origins and Development, Fig. 3 Scanning electron micrograph of finger millet grain, dorsal view

studies in India due to confusion of the husk of *Setaria/Brachiaria* with grain surface of *Eleusine* and an anachronistic assumption that finger millet is the most widespread small-grained millet in India (see Fuller 2003). Therefore, within South Asian archaeobotany, the antiquity and distribution of this cereal remains controversial.

Timing and Tracking Domestication

Archaeobotanical evidence does not yet shed much light on where or when finger millet was brought into cultivation (Giblin and Fuller 2011). The earliest finds in Africa are only just over 2,000 BP from Nigeria and northern Ethiopia. Most evidence in Ethiopia is post-Axumite, while further south in Eastern Africa, it is widespread from Middle Iron Age times after c. CE 600 (Giblin and Fuller 2011). As a result of concerns over identification, the date at which finger millet arrived in India from Africa remains contentious, but it is certainly present by the end of the second millennium BCE (Fuller 2011). Some claims would put it in India as early as c. 2,500 BCE (Weber 1991). On most Indian sites where it has so far been found, both prehistoric and early historic levels occur, raising the possibility of later intrusive grains. It also appears to be a fairly minor component by comparisons to other millets on most sites, suggesting that its rise to importance only took place in the past 1,500 years or so. There is no archaeological evidence yet that sheds light on its spread through the Himalayas or eastwards to south China and Southeast Asia.

Fiorelli, Giuseppe

Dorothy Pearl Kelly
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

The Italian archaeologist Giuseppe Fiorelli was born in Naples on 8th June, 1823. Educated in Naples, Fiorelli achieved a degree in legal studies by the time he was 18, but chose a career in archaeology instead because of his passion for ancient cultures (Dwyer 2010: 25). In addition to this, Fiorelli had a background in the study of epigraphy, numismatics and pre-Romantic Italic languages (Dwyer 2010: 25). He was also an excellent antiquarian and had solid scientific knowledge (Cooley and Cooley 2004: 192).

By the age of 20 Fiorelli had published an article on numismatics in an archaeological journal. In 1847, at the age of 24, he secured the position of Inspector of the Pompeii excavations (Dwyer 2010: 25). His post was terminated in 1848 due to his activities during the political uprising in Italy (Cooley and Cooley 2004: 192). In 1849 Giuseppe Fiorelli was detained as a political prisoner under Bourbon rule. It was during this sentence that Fiorelli assembled manuscript notes from previous excavators of the site, and transformed them into a three-volume work entitled *History of Pompeian Antiquities* (Cooley and Cooley 2004: 192). Fiorelli's professional life suffered as a result of regulations set in place by organisations and political parties during the 1840s and 1850s. During this time, publications that concerned sites in the Kingdome of Naples needed the official approval of the Royal Herculaneum Academy. In 1850 when Fiorelli published the first volume of an intended series of eight books, his work was confiscated and burned by the authorities (Cooley and Cooley 2004: 192).

While these events limited Fiorelli's professional life to a degree, he found employment through Count Leopold of Syracuse, who hired him to work as a private secretary between 1853 and 1860. During this period Fiorelli excavated and published works relating to Cumae (Cooley and Cooley 2004: 192). In 1863, following the fall of the Bourbon dynasty, Fiorelli became superintendent of excavations at Pompeii, where he developed a unique approach to conserving the material remains of this ancient city (Amery and Curran 2002: 43). Fiorelli was appointed as director of the National Archaeological Museum in Naples, a position that had been previously filled by the French author Alexandre Dumas. In 1875, after extensive and groundbreaking work at Pompeii, Fiorelli successfully published his findings known as '*Descrizione di Pompei*', or 'Description of Pompeii'. In the same year he was appointed as General Director of Antiquities and Fine Arts in Rome (Amery and Curran 2002: 43). After a successful and groundbreaking career as an archaeologist, Giuseppe Fiorelli died at the age of seventy-six in Naples on 28th January, 1896.

Major Accomplishments

Giuseppe Fiorelli's wealth of knowledge influenced his approach to archaeology and gave

rise to new methods in archaeological practice, particularly in regards to excavation. One of his major achievements concerned development of innovative techniques for the excavation of ancient structures at Pompeii. The archaeological approach to excavating houses at that time was destructive and recorded little information. The earth and debris would be shoveled out of the structure at ground level, and any material remains of interest were set aside with no documentation or context (Amery and Curran 2002: 44). Due to a lack of reinforcement, these buildings would often collapse, causing further damage and inducing a vast loss of information (Amery and Curran 2002: 44). In response to this, Guiseppe Fiorelli developed a new system of excavation in which every structure was uncovered by removing the individual strata from the highest point of the site to the original ground level. Fiorelli's innovation allowed buildings that were being uncovered at Pompeii to maintain their structural integrity, thus salvaging and yielding more information for archaeologists (Amery and Curran 2002: 44).

Guiseppe Fiorelli's second major accomplishment in archaeology involved the development of a method for preserving cavities in the layers of ash and soil of Pompeii. Fiorelli recognized that these air pockets were impressions of humans, animals and other organic material that had been encased in ash and eventually decomposed over time, leaving distinct impressions (Amery and Curran 2002: 45). When such cavities were located Fiorelli organized for plaster to be poured into them. Once it hardened and the debris was cleared away casts of human bodies and animals were exposed. This technique, known as Fiorelli's process, revealed the true nature of the terror that engulfed the inhabitants of Pompeii when Mount Vesuvius erupted. To this day, it is one of the most poignant features of the excavations (Amery and Curran 2002: 45; Luongoa et al. 2003).

Giuseppe Fiorelli also brought order to the way in which excavations were managed, in terms of the topography of Pompeii. He divided the city into *regions* and *insulae*, or regions and blocks, so that every region and block was numbered and could be easily identified (Amery and Curran 2002: 45). This enabled the specific descriptions of building locations and their proximity to other structures to be accurately recorded, which further aided any map making and drawing plans. Archaeologists who continued Fiorelli's work maintained the use of this grid-like system which it is still in use today in archaeological work (Amery and Curran 2002: 44).

First Australians: Origins

Michael C. Westaway and David Lambert
Environmental Futures Centre, Griffith University, Nathan, QLD, Australia

Introduction

Many Aboriginal people view that their ancestry is closely linked with the creation of the Australian landscape during the period they refer

to as "the Dreaming." From a scientific perspective, this is in some ways complementary to the picture from archaeology. The Australian landscape, with its diverse and changing environments during the dramatic fluctuations over the last 50,000 years, has been assumed to play a significant role in influencing and forming the diverse morphology of the modern Aboriginal people. Understanding the biological basis that underpins these diverse and changing morphologies is one of the key challenges confronting Australian palaeoanthropology.

In general terms, the picture from the archaeological record identifies that Aboriginal origins are external to Australasia and what would appear to be emerging from the global picture is that within the last 100,000 years of human evolution, several species of hominins once coexisted across the globe at the time of the great *Homo sapiens* expansion. The known species include: *Homo floresiensis*, *Homo neanderthalensis* (which may or may not include the Denisovans), and possibly also *Homo erectus*. What remains unclear is how these species interacted, although the evidence from ancient DNA (aDNA) now indicates that some degree of assimilation of Neanderthals and/or the Denisovans did occur, albeit on a small scale. The First Australians play a key role in the understanding of modern human origins globally and within their aDNA would appear to be preserved the signature of both Neanderthals (Yotova et al. 2011) and Denisovans.

Historical Background

Huxley (1863) published the first study comparing Aboriginal skeletal biology to the fossil record in an attempt to explain modern human origins. At the time, he compared an Aboriginal calotte to that of the recently found Neanderthal fossils where he observed a number of similar characteristics. The general opinion at the time suggested that as Aboriginal people still lived in a hunter-gatherer state, then it was likely that they more closely represented the original state of humankind. They were in the words of numerous scientists of the late nineteenth century "living fossils." This was a position also largely supported by the social anthropology of the time, as reflected in the works of such scholars as Tylor (1873).

Of course, there were exceptions to this position, and indeed, some physical anthropologists considered the Aboriginal peoples position in the human evolutionary story in a different light. Klaatsch, the German physical anthropologist known for his pre-World War I work on the Neanderthals, and inspired by Huxley's (1863) comparisons with the Neanderthal calotte, argued for ancient human origins in Southeast Asia. He suggested that the first modern humans evolved in Southeast Asia and were: (a) the ancestors of the Aurignacians (an archaeological culture of the Upper Paleolithic); (b) the population responsible for the extinction of the Neanderthals; and (c) the colonists of Australia. Klaatsch made a detailed study of a range of Australian crania indicating that the first modern humans were still represented in Aboriginal populations. The Great War saw a dramatic decline in interest in German science and British models came to dominate debates. Sir Arthur Keith was the preeminent physical anthropologist of the time and greatly influenced the course of American physical anthropology through his training of Earnest Hooton, a preeminent United States physical anthropologist in the first half of the twentieth century, Earnest Hooton (Brace 2005). It was a student of Hootons, Joseph Birdsell, who was to establish a theory of human evolution known as the "Trihybrid" model of Aboriginal origins that was to dominate debate and influence scientific and popular opinion for almost 40 years. Birdsell (1967, 1977) argued that three successive waves of migrants arrived in Australia, the first represented by the Barrineans (a 'Negrito' - based population), the next the Murrayineans (Aboriginal people that inhabited the Murray River corridor), and the latest the Carpenterians (people of tall stature from Lake Carpentaria). Opposing Birdsell's view was that of Abbie, who argued that the variation that was present represents homogeneity in a population adapted over a long period of time to differing environments (Abbie 1951, 1963, 1966) (Fig. 1).

The other main interpretation was initiated by Sir Arthur Keith (1936), building on the idea and

First Australians: Origins, Fig. 1 Birdsell's map illustrating the northern and southern migrational routes through Sunda into Sahul

discoveries of Eugene Dubois. Dubois (1922) suggested that there was an evolutionary sequence of regional continuity represented in Sunda and Sahul by the Trinil, Sangiran, and Ngandong *Homo erectus* sequence through to the Wajak *Homo sapiens* to Aboriginal Australians. This idea was further developed by Weidenreich (1943) who is often credited with the theory of regional continuity. He added to the model the Keilor fossil to extend the regional evolutionary sequence into Pleistocene Sahul. The concept of a close evolutionary connection with Java was further developed by the work of Macintosh (1965) who referred to the "mark of Ancient Java" being present in Australian populations. However, it was Macintosh's student Alan Thorne who was to become the most prominent supporter of this theory through the development of his own brand of multiregional continuity known as the Di-Hybrid view of Aboriginal origins. Others such as Howells (1973) considered that two differing morphologies representing two different populations were most likely represented in the Australian fossil record. This idea was developed in far greater depth, in both time and space by Thorne who through his survey and excavations at the Willandra Lakes and Kow Swamp developed an extensive fossil series that brought Australian palaeoanthropology into the global scene. It also played an important role in inspiring a generation of new Australian biological anthropologists working out of schools of archaeology as opposed to schools of anatomy.

Key Issues/Current Debates

Interpreting the Fossil Trail to Sahul

While local evolution from more ancient predecessors has been claimed for Sunda and Sahul in the past, it is only in Africa that we see transitional premodern and modern human fossil forms. The consensus is that it is only in Africa that we can trace the origins of the First Australians. The first appearance of *Homo sapiens* in the fossil record occurs in Eastern Africa in Ethiopia around 190 ka with the Omo and Herto fossils. The first appearance of *Homo sapiens* outside of Africa is in the

Levant with the Jebel Skhūl and Jebel Qafzeh fossil series generally thought to date between 110 and 90 ka. The general assessment is that this population seems to have been replaced sometime after 90 ka by Neanderthals who returned to South West Asia (Tchernov 1998). Curiously, there seems to have been little consideration of the possibility that this initial range extension of *Homo sapiens* (some 100 ka) may have extended further east than the Levant. This possibility has received little attention perhaps because of the uncertainly regarding the dates of the Liujiang fossil and isolated teeth from Punung in Java (120 ka), together with the fact that there is no other fossil evidence of *Homo sapiens* in Asia before 50 ka. The available record for *Homo sapiens* prior to the Marine Isotope Stage (MIS) 2 between Africa and Australia is currently very sparse and provides little evidence of the evolution of modern humans in the Asian region.

As a result of the scarcity of the modern human fossil record, much of the interpretation of the human fossil record from Sahul in the past has depended upon the record of more archaic hominins from neighboring Sunda, the land mass incorporating the islands of Southeast Asia. As noted in the preceding section, the record from Java played a primary role in influencing our understanding of Aboriginal origins for much of the twentieth century. For many years, a number of variations of multiregional continuity proposed that Aboriginal origins were closely associated with the evolution of *Homo erectus*, as known from the extensive record from Java at sites such as Trinil, Sangiran, and Ngandong. Despite earlier claims of a late Pleistocene age for *Homo erectus* (Swisher et al. 1996), there would currently appear to be no evidence to suggest that *Homo erectus* survived beyond the middle Pleistocene (Westaway and Groves 2009; Indriati et al. 2011). We do not presently know from the available evidence if *H. erectus* and *H. sapiens* overlapped in time.

However, there is evidence from the Lesser Sunda Islands that suggests that at least two hominin species perhaps coexisted within Sunda. Several specimens of *Homo floresiensis* recovered from Liang Bua, Flores, have revealed that a small bodied hominin continued in this island refuge perhaps as late as 18 ka (Morwood et al. 2004). The most parsimonious explanation for this hominin is that it is a species predating *Homo erectus*. Descriptions of the available post crania (e.g., Jungers et al. 2009) also support the view that *Homo floresiensis* derived from a pre-ergaster/erectus hominin.

In terms of other archaic hominins from the Asian region on the fossil trail to Australia, there is very little. The Namarda fossil is the only representative of a post ergaster/erectus hominin from the Asian region on the trail to Australia and has been interpreted as an Indian representative of *Homo heidelbergensis* (Groves 1989). More recently, the discovery of a new hominin from aDNA recovered from a phalange has revolutionized our idea of hominin interaction during the last 100,000 years. Nothing is known of the morphology of this new hominin identified from the Denisovan Cave in Siberia, and neither do we know anything much regarding its geographical distribution.

Our understanding of the distribution of *Homo sapiens* is limited as there are very few modern human fossils dating to the crucial period of Marine Isotope Stage 3 when Southeast Asia is alleged to have been colonized by *Homo sapiens*. Fossils include the Niah skull dated to 40 ka. The record for *Homo sapiens* in Sunda dating to the Pleistocene is minimal to say the least. The Wajak fossils have been dated as terminal Pleistocene (although this age determination is by no means definitive) and as noted above their morphology is often compared to the Keilor fossil discovered on the outskirts of Melbourne, Victoria. Another intriguing specimen suggested to be representative of *H. sapiens* is known from Punung, dated to 120 ka and it is known only from teeth.

The First Seafarers

Of all the continents colonized by modern humans, Australia is the only one that was not connected at some stage during the Pleistocene by a land bridge. Its colonization has always required the use of water craft capable of a number of significant sea crossings. Birdsell (1977) was the first to summarize these sea routes. The shortest

leg of the journey taking the northern route would have involved a sea journey of around 70 km. Much planning and preparation was required for the colonization and it is likely that a familiarity with the sea and an understanding of the type of signs to look for (such as smoke well over the horizon and the movement of migratory birds) were part of the intellectual tool kit required to undertake long-distance sea journeys. This process has been identified as the earliest example of modern human cognition (Noble and Davidson 1996; Davidson 2010). Watercrafts were most likely rafts constructed from bamboo. The absence of bamboo on mainland Australia perhaps made return journeys quite difficult although there is evidence in the archaeological record, such as the early appearance of edge ground axes and the presence of CusCus in East Timor, which indicates that return journeys may have been made. The survival of the archaic hominin *Homo floresiensis* along the southern route on Flores perhaps indicates that the northern route through the Birds Head of Papua was taken in the initial colonization of Sahul (Balme et al. 2009) (Fig. 2).

The Australian Fossil Human Record

The extent of the Pleistocene *Homo sapiens* fossil record from Sahul is quite considerable when compared to the regions to the north within the tropical belt. This is in large part an outcome of taphonomy, the large extinct lake systems that covered much of Southeast Australia provided excellent conditions for the fossilization of carefully interred human burials, of which there must have been many thousands. Australia has a rich record of human fossils dating to the Pleistocene, although the record was built over a century. The initial record was patchy, with the discovery of Talgai in 1886 and the recognition of its importance being identified at the British Academy of Science meeting in 1914. It was followed by the discovery of the Cohuna fossil in 1925 and Keilor in 1940 (both from Victoria). Numerous other key specimens were collected by George Murray Black during the 1930s including probable Pleistocene fossils from Coobool Creek and Lake Benanee along the Murray River. Several other key specimens including those from Lake Nitchie and Mosgiel reported in the 1960s. It was not until the concerted effort of Alan Thorne that Australia

First Australians: Origins, Fig. 2 A Lardil man paddling a "walba." The vessel was built in 2 days from rope stripped from hibiscus, white mangrove logs, and the paddle constructed from a splayed mangrove root. Lardil men would traditionally tie rope around their waist so that they could make repairs to the craft at sea. Rafts provided a far more stable platform in choppy seas than canoes. It is likely that similar (but larger) rafts made from bamboo lashed together with rope made by plant fibers represented the first vessels to bring people to Australia

First Australians: Origins, Fig. 3 The Cohuna fossil found in 1925. The frontal flattening, initially thought to be a trait shared with *Homo erectus*, is now recognized as a result of deliberate cranial deformation. (Photo Colin Groves ANU)

started to accumulate a larger fossil sequence from more controlled stratigraphic contexts. Between 1968 and 1988, Thorne and colleagues amassed a fossils series representing over 160 individuals first from Kow Swamp and then the Willandra Lakes (Fig. 3).

One of the most intriguing elements of the Australian fossil record is its considerable diversity. Arguments have been based around the two "morph" types, defined by many as robust and gracile, that were the foundation of Thorne's Dihybrid model. Others have argued that the differences are a result of sexual dimorphism while others still have indicated that the variation in morphology may in fact be the result of microevolutionary change and genetic isolation during the period of climatic stress at the Last Glacial Maximum. What is of particular interest is the general chronological pattern that emerges from the assessment of the burial age range with cranial robusticity appearing no earlier than 25 ka. This age range correlates with the onset of glacial aridity, and suggests that robusticity may in fact be influenced by the harsh environmental stress associated with the LGM. The proposal that cranial robusticity may be associated with the LGM is supported by recent age ranges from Kow Swamp (Stone and Cupper 2003). Certainly sexual dimorphism plays a role in morphological expression (Pardoe 1991), but the harsh climatic conditions of the LGM may have applied evolutionary pressure on the series also. Gilligan and Bulbeck (2007) have suggested that, based on the large Birdsell's (1993) late Holocene Aboriginal data set, a considerable amount of morphological variation within the Australian Aboriginal population can be explained in terms of adaptations to the physical environment. Correlations (particularly with temperature) are found for measures relating to body shape, head size and shape, limb lengths, and limb proportions. These observations are in accordance with correlations predictable from biological principles of long-term human adjustment to environmental conditions. A larger cranial shape is often correlated with colder climates (Guglielmino-Matess et al. 1979). They note that exposure to cooler conditions during the late Pleistocene, particularly in the southern part of Sahul, might have amplified regional variation in evolutionary or phenotypic change in response to thermal conditions at the time (Fig. 4).

The earliest fossils from Sahul which can be considered representative of the First Australians are those of Mungo Woman (WLH 1) and Man (WLH 3) dating to soon after first human arrival approximately 42 ka ago. These individuals have very lightly built crania with vault thickness not exceeding 7 mm. Mungo Man does have very robust postcrania, the general dimensions supporting the assessment that the remains are those of a male. An intriguing component of WLH3's morphology is his high frontal curvature index and minimal development of the superciliary ridges. This is a pattern quite different to that in later Australian male fossils and it is primarily these characters that have resulted in Brown's (2000) assertion that these represent the remains of a female. This is not supported by the dimensions of WLH 3's postcrania (Durband et al. 2009) (Fig. 5).

There are 23 other fossils that preserve enough of their cranial anatomy to provide an insight into the range of cranial variation in the Willandra Lakes. This represents an important series as it provides us with an insight into population variation at least around the time of the LGM, rather than just simply depending on one or two key

First Australians: Origins, Fig. 4 Theorized representation of the emergence of cranial robusticity associated with the onset of the Last Glacial Maximum

specimens for our understanding of cranial variation. Some of these individuals are very robust, including WLH 19 and the most heavily studied specimen WLH 50. Robust characters do not appear to be restricted to males, with WLH 45 (established from female characters in the pelvis) also preserving characters that could be assessed as robust. From the available dates, cranial robusticity correlates with the Last Glacial Maximum and, as suggested by Bulbeck (2001), may reflect evolutionary or at least phenotypic processes in response to significant climatic change (Fig. 6).

The suggestion that cranial robusticity may be associated with the environmental stress of the LGM is further supported by the evidence from Kow Swamp, located south of the Murray River some 400 km Southeast from the Willandra Lakes. This site was redated to between 19 and 21 ka through a more recent assessment of the site (Stone and Cupper 2003). Criticisms have been raised that this series of OSL ages date the surrounding units and not the burials. However, as all burials (with the exception of KS 15) are sealed in the Cohuna silts (Stone and Cupper 2003), this indicates that the above age range is reliable. Another very significant element of the series is that it preserves the earliest evidence of the practice of artificial cranial deformation in the world. Cranial deformation has exaggerated some of the characters, such as the angle of the receding frontal, which has resulted in the more archaic appearance of these fossil human remains (Fig. 7).

First Australians: Origins, Fig. 5 Lateral view of WLH 3. There is very minimal development of the lateral trigone and superciliary ridge. Interestingly, the frontal curvature index is quite high when compared to later Australian fossils. (Photo: Dragi Markovic, NMA)

Further to the west downstream along the Murray are a series of other significant burial sites that have quite often been described as very early

First Australians: Origins, Fig. 6 Lateral view of WLH 50. This specimen represents the most robust fossil cranium yet known from the fossil record. Thickening in the diploë suggests that there has been some hematopoietic reinforcement in the cortical bone as a result of pathology. (Photo: Dragi Markovic, NMA)

First Australians: Origins, Fig. 7 Kow Swamp 1. Like the Cohuna fossil, the heavily receding frontal is the result of artificial cranial deformation and not admixture with more archaic hominins from Sunda (Cast, photo Arthur Durband)

cemeteries. Little detail exists to support the suggestion that cemeteries were in existence in the Late Pleistocene-Early Holocene, and these are likely to represent individual and small group burials scattered over many centuries, rather than evidence of Pleistocene cemeteries per se. Coobool Creek is one of the more significant of these sites (although its precise location is now lost) and like Kow Swamp, it preserves crania, demonstrating artificial cranial deformation.

First Australians: Origins, Fig. 8 Nacurrie 2. This heavily mineralized calotte preserves a well-defined superciliary ridge and mental trigone. (Photo NMA)

Existing absolute dates suggest that these individuals are terminal Pleistocene. The Nacurrie calottes, 1 and 2, are often considered as part of the Coobool Creek series. These heavily mineralized crania also preserve evidence of cranial deformation. The Roonka fossil series (Pretty 1977) provides important insights into prehistoric cemeteries as it represents one of the only such site types to be archaeologically excavated (the other is the late Holocene cemetery site at Broadbeach). The site complex is defined into three stages, Roonka I (20–8 ka), Roonka II (8–4 ka), and Roonka III (4–2 ka). Over 216 burials have been excavated and there are over 250 age determinations. Only one burial EB2 F8 has been excavated that has been established as Pleistocene in age, bracketed between two OSL ages at 20–16 ka (Fig. 8).

Another key fossil that has featured prominently in debates was discovered on the northern outskirts of Melbourne, Victoria, in the Pleistocene terraces of the Maribyrnong River. This is the site of the discovery of the Keilor skull in a quarry in 1940 (Wunderly 1943). Keilor Man is intriguing in that he represents a large individual; however, he does not preserve robust cranial characters. Historically, Keilor was often compared to the Wajak crania from Java, and it is true that they share a very similar general morphology.

Numerous other fossils have been recovered that preserve robust cranial morphology that

extend into the early Holocene. These include two specimens from Western New South Wales, Mossgiel, and Lake Nitchie. Lake Nitchie is an extraordinary burial in that it also preserves a necklace representing the teeth of 47 different Tasmanian Devils (*Sarcophilus harrisii*). One further robust Australian fossil that requires further discussion is the individual from Cossack. It represents the only known fossil representative of Western Australia. The male cranium was discovered in 1972 and bears robust characters that have been identified as similar to the robust individuals from the Kow Swamp series. Cranial vault thickness and the low frontal curvature index sits closely to the robust individuals from the Kow Swamp series (Freedman and Lofgren 1979), and yet, this individual's age range is from the mid to (more likely) late Holocene. If the cranium dates to the last few thousand years and the reconstruction is accurate, it suggests that some robust characters continued to be present much later in prehistory and may be representative of adaptation to harsh environmental conditions, rather than a late Pleistocene or early Holocene cranial morphology. There are however numerous issues in the published image of the Cossack reconstruction, including the positioning of the malar which impacts on the reconstruction of the shape of the orbit, which has resulted in placing the fossil in the incorrect orientation of the Frankfurt Horizontal Plain. In addition, the reconstruction of the position of the maxilla would seem to exaggerate prognathism in the fossil, and this is supported by the angle of the occlusal plain in the teeth, which angles unnaturally upward. The superciliary region is also not as well developed as the more robust specimens such as WLH 50, Kow Swamp 1 and 5, and Nacurrie 2. It lacks any sign of a sulcus behind the superciliary ridges. A reconstruction of Cossack is overdue and if undertaken will in all likelihood reduce exaggerated robust characters such as midfacial prognathism and indeed the orientation that the frontal is often illustrated (Fig. 9).

In the last several years, a number of important fossil discoveries from Papua New Guinea have helped build a picture of Australian morphology in northern most Sahul. A semicomplete burial excavated from Liang Lemdubu dating to 18,000 years provides an important insight into the morphology of people living in this region during the peak of the Last Glacial Maximum. Unlike the Willandra which at this time was under severe environmental stress, Lemdubu woman was living well within the tropical belt, the Aru Archipelago of West Papua being at the time adjacent to the coast (Hope and Aplin 2005) (Fig. 10).

First Australians: Origins, Fig. 9 Cossack Man. It is probable that the prognathism is exaggerated in this reconstruction giving the fossil a more archaic appearance. In all likelihood the face was probably positioned more posteriorly beneath the cranial vault. This is supported by the angle of the occlusal plain in the above reconstruction. (From Freedman and Lofgren 1979)

The Emerging Picture from Studies of Aboriginal DNA

The evidence from DNA studies is providing new insights into our understanding of the origins of the First Australians that were not possible previously from studies of the fossil and osteological record. While in the past there has been a number of studies that have examined variation in Aboriginal blood genetic markers (blood groups, leukocyte, serum protein groups, and red blood cell enzymes), more recent Aboriginal genomic studies have altered our understanding of the early population history of Australia. Two lines of investigation have been undertaken that have revealed the genetic composition of the First Australians. Studies on living populations have

First Australians: Origins, Fig. 10 Lemdubu woman (Bulbeck 2005)

distinguished unique Y chromosome and mtDNA haplotypes in Aboriginal Australia which indicate that migrations into Australia through Asia predate 50 ka (Keinan et al. 2007; Gutenkunst et al. 2009; van Holst Pellekaan 2011). However, like all other non-African populations, all Aboriginal Australian mtDNA studies demonstrate that their ancestry can be traced to a single L3 haplotype. One important component of mtDNA studies from Melanesia, as highlighted by Davidson (2010), is that the genetic evidence indicates two possible migration events, with a separation between the mtDNA of the colonists of north and east Papua New Guinea, with those from southern Sahul. Indeed it would appear that the haplotypes from Melanesia represent earlier haplotypes from those present in southern Sahul (Merriwether et al. 2005). The Australian mt haplogroups S, O, and M42a are not shared with New Guinea on current evidence and this, together with shared haplogroups P and Q, has been interpreted as indicating separate origins of Australian and New Guinea people, while at the same time different migration histories of these separate groups of colonizers. Van Holst Pellekaan (2008) has raised the question: Do the differences in haplogroups indicate that there were different entry points into Australia. This proposition has been explored by Davidson in reference to archaeological, ethnographic, and linguistic evidence (2010 and in press). In particular, Davidson (2013) suggests that separate studies of mtDNA (van Holst Pellekaan et al. 2006) and of mtDNA and Y chromosome (Hudjashov et al. 2007) show consistently that variations within the region of Sahul have deep roots going back to the first colonization of the continent at 40 to 50 kya. We agree that, taken together, these data are consistent with the possibility of separate colonizations along Birdsell's northern and southern colonization routes to Sahul (Fig. 1).

The recent sequencing of genomes of *Homo neanderthalensis* and of Denisovans and their subsequent comparison with modern human genomes has been suggested to indicate hybridization with modern human populations, subsequent to their movement out of Africa (Reich et al. 2010). Specifically, it has been proposed that 1–4% of the Eurasian genome derives from Neanderthal and 5–8% of the Melanesian genome is derived from Denisovan and Neanderthal sequences (Reich et al. 2010; Abi-Rached et al. 2011; Mendez et al. 2012).

This latest evidence for hybridization from genomic studies has been based on the number of derived shared SNPs from either the Neanderthal or Denisovan samples, compared with those of selected modern individuals representing the major population groups. These studies have shown that both the Denisovan and Neanderthal samples share more derived SNPs with Eurasian and Melanesian populations than they do with African. It has been argued that this indicates hybridization with these populations subsequent to their migration out of Africa (Reich et al. 2010; Lalueza-Fox and Gilbert 2011; Stoneking and Krause 2011). In support of this view, recent simulations conducted by Hammer et al. (2011) allowed the authors to reject the null model of no admixture between *H. sapiens* and archaic forms. Instead they suggest that contemporary African populations have retained a small proportion of genetic material (~2%) that introgressed ~35 ka from an archaic population that split from the ancestors of anatomically modern humans ~700 ka. One particular locus ~31 kb in length on chromosome 4 appears to have introgressed into modern Africans from an unknown and now extinct taxon that may have lived in central Africa.

This issue had been debated extensively in the past with partial mitochondrial DNA sequences suggesting that there was no evidence of hybridization (Serre et al. 2004), in contrast to some morphological studies (Bilsborough 1972). Wall and coworkers have, for some time, argued that, based on haplotype length data, there is strong evidence for ancient admixture in both European and West African populations, with contributions to the modern *H. sapiens* gene pool of at least 5%. This issue was important because the integrity of the Out of Africa (OOA) theory, in its formal sense, was at stake. That is the proposal that anatomically modern humans evolved in Africa 200,000–150,000 years ago and that they subsequently migrated out of Africa 100,000–60,000 years ago, displacing other archaic hominins (with no hybridization), giving rise to all current human populations. Hence, any evidence for hybridization between modern humans and any archaic group(s) is contrary to that view.

The now recognized relatively large contribution of archaic DNA to modern human is in stark contrast to the absence of any evidence for hybridization from uniparental Neanderthal of Denisovan markers in modern or even early modern populations (Ghirotto et al. 2011). However, Currat and Excoffier (2011) suggested that nuclear DNA introgression is compatible with the observed absence of Neanderthal mitochondrial lineages among contemporary humans. These authors concluded that an interbreeding success smaller than 2% for Neanderthal human hybrids is fully compatible with limited Neanderthal nuclear introgression and with no introgression of mtDNA. The authors note that they obtained comparable estimates of maximum interbreeding success rates (<3%) in an earlier simulation study that focused on the absence of Neanderthal mtDNA introgression into modern humans (Currat and Excoffier 2004).

In addition, the robustness of the data themselves has been questioned including the possibility of human contamination, and the confounding effects of ascertainment bias and/or genetic drift (Reich et al. 2010; Skoglund and Jakobsson 2011). The latter authors (Skoglund and Jakobsson 2011) showed that genetic similarity to Neanderthal increases with increasing distance from Africa. However, and conversely to expectation, a significant gene flow was detected between the Denisovan and Southeast Asians. The former authors (Reich et al. 2010) suggested that similarities between modern human and the Denisovan and Neanderthal genomes may simply be the result of parallel substitution, or convergent evolution and that this might be enough to influence archaic hominin/modern human associations by a few percent, perhaps ample to infer hybridization events.

Specifically with respect to Australian Aboriginals, investigations into aDNA of subfossil remains from the Willandra Lakes and Kow Swamp, these have revealed some intriguing insights into the population history of Australia. The evidence from aDNA has indicated that two of the sampled individuals, WLH 3 and KS 8, lie outside of the range of modern Aboriginal genomic variation, it being argued that they have non-L3 ancestry (Adcock et al. 2001). This position has been the subject of considerable criticism, (Groves 2001; Relethford 2001; Cameron and Groves 2004) and it is by nuclear mitochondrial sequences (numts) may have resulted in the observed mtDNA sequence or that it may in fact represent modern contamination (Colgan 2001; Trueman 2001; Cameron and Groves 2004). A current study being undertaken by the authors is expanding on the original aDNA study undertaken on the Willandra fossil series to assess if the results can be replicated and if so an ultimate goal is to determine if a signature for Neanderthals or Denisovans can be detected in any recovered sequences.

Future Directions

It would seem that aDNA research is opening up new avenues of understanding on the origins of the First Australians. If the original study of the aDNA of Mungo Man is correct, and does not represent modern contamination, Mungo Man (WLH 3) and KS 8 represent a distinct lineage. If accurate, this has enormous bearing on our

understanding of the population history of Sahul and indeed the evolutionary history of modern humans. The very gracile cranial features, including a reduced superciliary region and high frontal, may not simply represent variation within a homogenous population but could in fact represent a more gracile morphology, represented also by the Niah fossil from Borneo which supports the hypothesis that the first significant population movement into Australasia was represented by a lightly built population (Bulbeck and O'Connor 2011). Perhaps the more robust characters that we see in the once rich fossil record of Sahul represent a later movement into Asia. Could this include a phenotype that incorporated the assimilation of Denisovan and Neanderthal genes that reintroduced a robust cranial morphological component? As discussed above, the available evidence from the genome indicates that genetic exchange between modern and archaic people was on such a small scale that it is unlikely to have had any influence on the expression of cranial morphology. The differences in haplogroups between Aboriginal and Melanesian populations indicate that there may have been different entry points into Sahul during the Late Pleistocene, but it is not clear how this could relate to diversity in Pleistocene cranial form.

An alternative hypothesis is that the robust cranial morphology is a character somehow selected for in environments of climatic stress, or that it represents the results of a process of genetic drift in some populations. It is interesting that this morphology is present from 25 to 10 ka supports the proposal that it is associated with the climatic changes of the LGM. Higher chronological resolution is required in order to support this hypothesis. A major obstacle to our understanding, as pointed out by Pardoe (1991), is that until we have larger samples that provide us with an understanding of variation within a certain point in time, as opposed to simply a picture from one or two key fossils from a known time period, our understanding of evolutionary processes and possible migratory events will remain limited. This is a problem that has been exacerbated by the repatriation and reburial of numerous key fossil specimens that are no longer available for future analysis. The concept of a "keeping place" for such important collections (such as the 100+ individuals from the Willandra fossil series) would represent a key achievement as it provides a positive compromise to both science and Aboriginal cultural responsibilities for the deceased.

The archaeological and linguistic record for later migrations in the Holocene provides yet another complex picture to be investigated. It is clear that there was a linguistic expansion which is argued to have occurred in the mid-Holocene, but what is unclear from the available evidence is whether this had any impact on the Aboriginal phenotype through a pulse of new genes into Sahul. These questions and more will hopefully be the focus of future collaborative efforts between archaeologist, geneticists, biological anthropologists, and traditional owners as we continue to expand on our understanding of one of the more intriguing chapters on the global dispersal of our species.

Flannery, Kent Vaughn

Robert J. Sharer
Department of Anthropology, University of Pennsylvania, Philadelphia, PA, USA

Basic Biographical Information

Kent Vaughn Flannery was born in 1934 and grew up in the Chesapeake Bay region of Maryland. One of his high school teachers instilled in him a strong interest in zoology, ecology, and evolution. Flannery took advantage of the University of Chicago's "early entrant" program to enroll after his sophomore year of high school, receiving his B.A. in 1954. He then began studying for an M.A. in zoology. In 1957–1958, Flannery spent a year in Mexico collecting data for his thesis. He took archaeology courses at the Universidad de las Américas and participated in excavations in the Valley of Oaxaca. On his return to Chicago, he switched to anthropology. In 1960, Robert Braidwood took him to Iran as a field assistant to his staff zoologist, Charles A. Reed along with fellow student Frank Hole. Flannery wrote a Master's thesis (1961) in which he distinguished wild and domestic pigs from Near Eastern Neolithic sites. In 1961 Hole and Flannery returned to Iran to conduct excavations at Paleolithic and Prepottery Neolithic sites. They were joined in 1963 by James Neeley (Hole et al. 1969).

Flannery maintained his interest in Mesoamerica by working in Chiapas, Mexico, with Robert McC. Adams and at Ocós, Guatemala, with Michael D. Coe (Coe and Flannery 1967). Enroute to Guatemala, Coe and Flannery visited Richard S. MacNeish's project in Mexico's Tehuacán Valley. Once MacNeish learned that Flannery was an archaeozoologist and had worked with Braidwood on the origins of agriculture and animal domestication, he invited Flannery to join the Tehuacán project. Flannery worked with MacNeish during 1962–1963 and his archaeozoological research was included in Volume One of *The Prehistory of the Tehuacán Valley* (1967). MacNeish also encouraged Flannery to use data from the Tehuacán Formative for his Ph.D. thesis (1964) at the University of Chicago.

Flannery was hired as Associate Curator of Mesoamerican Archaeology by the Smithsonian Institution in 1964. One of his first responsibilities was to begin a new research project. Remembering the many unexplored caves and Formative sites he had seen in the Valley of Oaxaca, Flannery obtained funds for a pilot season in Oaxaca. In 1966 Flannery (1986) excavated Guilá Naquitz Cave, which yielded what were then the New World's oldest preserved gourds and squash (8000 cal. BCE), runner beans (6400 cal. BCE), and maize (4250 cal. BCE). By 1967 Flannery began excavations at the large Oaxacan Formative site, San José Mogote, a task that would occupy him for 15 years. By 1972 he had been joined there by Joyce Marcus. Flannery and Marcus discovered that San José Mogote had been occupied continuously from the beginnings of village life in Oaxaca (c. 1600 cal. BCE) until its transformation into the largest civic-ceremonial center in the valley (600–500 cal. BCE) (Flannery and Marcus 1983; Marcus and Flannery 1996).

Flannery also collaborated with colleagues in the Andean region of South America. In the early 1970s he joined MacNeish in Ayacucho, Peru, analyzing faunal remains from sites like Jaywamachay Cave and Tukumachay Cave. During the 1980s he served as the faunal analyst on Joyce Marcus' project at Cerro Azul in Peru's Cañete Valley.

Major Accomplishments

Kent Flannery is a leader in applying an ecosystem approach to reconstructing the past, using archaeological and other relevant data to construct models that identify the adaptive changes in the relationships between human societies and their environments. This perspective has provided the basic theoretical foundation of Flannery's precedent-setting research in both the Middle East and Mesoamerica. Flannery (1968, 1972) united this approach with broader systems theory as it is applied across many scientific disciplines. He also adopted a broad multidimensional

perspective on ecosystems, which encompass all relationships maintained by a given society with its natural and cultural environment. In Flannery's view, information is one of the most crucial aspects of these relationships and identifying the what, how, and who involved in the flow of information is key to understanding how systems change.

Application of an ecosystem approach allowed Flannery to reconstruct the gradual transition from hunting and gathering subsistence to agriculture in the Valley of Oaxaca. Based on both archaeological and ethnographic data, Flannery (1968) proposed that the subsistence activities of early Oaxacan societies were regulated by seasonality and scheduling in a deviation-counteracting system that maintained the equilibrium of the subsistence system. Such a system has the potential to shift to a deviation-amplifying system when one or more components change causing the entire system to diverge from its former state – in this case, the trigger was genetic changes in several food plants that encouraged their increased exploitation, which ultimately led to a new subsistence system based on agriculture.

Throughout his career, Flannery has maintained a multidimensional perspective of change within human society. While acknowledging there are universal factors and processes at work, these are expressed in each case in unique ways, so that archaeology must seek and reconstruct the specific conditions and factors that were the crucial agents of change. To do this Flannery takes an inclusionary perspective to problem solving, considering all relevant archaeological, ecological, and anthropological data. In reconstructing the rise of complexity and urbanism in Oaxaca, Flannery led his colleagues and students to apply data from multiple disciplines to investigate each level within society – household, community, village, region, and area – to trace the unique developmental course toward increasing complexity. His inclusive perspective is also apparent in his application of ethnographic case studies to illuminate specific archaeological situations and provide insights into in the past based on similar ecological conditions and sociocultural factors. Flannery also applies ethnographic data from descendent native Zapotec communities in Oaxaca. A case in point is Flannery and Marcus's (1976, 1993), Marcus and Flannery (1994) studies of the crucial role of ideology to both the continuities and changes in pre-Columbian Oaxacan society which presaged developments in cognitive archaeology.

Flannery's career as an archaeologist is strongly shaped by his early background in science and his love of zoology, paleontology, and ecology. He continues to believe in a unique past that is knowable through the collection of empirical data, and the testing of universal models of social evolution. In his favorite theoretical model, agriculture began in an early Holocene period of "broad-spectrum" plant collecting and resulted from attempts to increase the density of certain plants while reducing travel time. A key turning point for early farmers was the privatization of storage; this allowed certain families to work harder and outstrip their neighbors, leading to social inequality. Flannery sees hereditary inequality as based not simply on economic advantage but also on ideological changes that justify inequality by giving it supernatural authority. He sees the origins of the world's first states as taking place in the context of competing hierarchical societies, when one of those societies gained an advantage that allowed it to subjugate the others. He is also a trenchant critic of fads in archaeological theory, especially those that pay limited attention to empirical data (Flannery 1982, 2006).

Perhaps the most important impact of Flannery's inclusive ecosystem approach can be seen in the recent shift in our concepts concerning the long-term evolution of human societies. While there certainly has never been a single unified "school of thought" within archaeology on cultural evolution (nor on any other perspective on the past, for that matter), the once popular assumption that human societies evolved along a course set by "prime movers" and "technological determinism" has given way to a more particularistic view of change that operates in an infinite number of ways under an infinite number of conditions – and can be reconstructed and understood by archaeology from an almost infinite number of approaches and theoretical perspectives. Seen in this light, Flannery's contribution to a

multidimensional ecosystems approach clearly has been one of the most essential "prime movers" in the evolution of American archaeology over the past half century.

Floors and Occupation Surface Analysis in Archaeology

Luis Barba Pingarrón
Laboratorio de Prospección Arqueológica,
Instituto de Investigaciones Antropológicas,
Universidad Nacional Autónoma de México,
Circuito exterior de Ciudad Universitaria,
Del. Coyoacán, México, DF, México

Introduction

In the same way modern carpets reflect the activities of their owners, occupation surfaces can tell many things about their users. Looking at the characteristics of the carpet once it has been removed from the floor of the whole house, one can realize that there are worn areas, consequence of intense transit and intact zones normally placed under heavy furniture. It is also possible to differentiate between clean areas and dirty parts of the carpet containing many residues spelt on the surface. Then, after a careful study of this carpet, it is possible to reconstruct most of the everyday activities of its users.

The same happens with the study of archaeological structures. In the case of occupation surfaces, it is now possible to use this approach to try to understand how people lived in the past. Traditionally, archaeological artifact distribution and architecture have suggested the way spaces were used. In recent times, chemical residues detected in the porous of floors have complemented this information and in many cases have confirmed preliminary inferences, but in some others, especially when there is no archaeological material on surface floors, they have been the unique indicator of the human activities carried out on the occupation surfaces.

In general terms, productive activities are easily recognized because the energy, the amount of materials involved, and the intensity of the activities produce a dramatic change in the archaeological context. However, occasional activities with limited material and energy involved are difficult to detect.

As a consequence of the use of chemical indicators, floors, which not so many years ago were disposable, became a new important archaeological material that has to be preserved, documented, and studied in order to recover valuable information concerning human activities carried out in the past.

Definition

Following well-established definitions, *soils* can be considered as the top of weathering profiles (vertical sequences) developed by the in-place physical and chemical alterations of preexisting sediments. If a sediment mass is stable, weathering at the surface creates horizons with distinctive physical and chemical properties that become superimposed on the previously deposited sediments. Soils are not sedimentary deposits, and normally support the vegetation allowing agriculture.

Sediments are produced by the weathering of rocks that are transported as solid particles or dissolved chemicals and are accumulated or precipitated in sedimentary environments. They are usually horizontal and nevertheless might be modified by tectonic movements.

In archaeological context, *fill dirt* describes the earthy material that is used to *fill in* a depression, but especially to level surfaces or to build mounds and archaeological structures in general.

Occupation surface is any surface that was used in the past. An example of these surfaces is the irregular level occupied by the inhabitants of a cave. One special case of this kind of surfaces is the *floor* that can be defined as a man-made nearly horizontal surface consisting of several layers of preparation and finishing. An outstanding example of floor is the lime-plastered floor (usually called stucco floor) that represents an important technological and architectonic development in Mesoamerica. Any occupation surface is able to preserve organic residues, but the reliability of the interpretation is maximized in lime-plastered floors.

As a result of the accumulation of thousands of analyses of floor samples, the importance of looking at floors as a new archaeological material became evident. During the first stage of chemical prospection, the object of study was the soil, but for the study of intrasite human activities, the focus changed to occupation surfaces and floors, man-made surfaces that behave in very different ways than soil. During an archaeological excavation, it is very important to establish the difference between fill earth, sediments, soil, and specially floors because the same chemical results can be interpreted in different ways depending on the kind of material under study.

In recent years, it has been demonstrated that chemical residues are well preserved in the porous texture of the floors, allowing their study after hundreds, even thousands, of years, and revealed the floor as an outstanding archaeological material that preserves information that has not been traditionally taken into account.

Historical Background

Hirth (1975) published a paper that put together the results of fieldwork carried out during 1972 in Manzanilla, Puebla and Chalcatzingo, Morelos, Mexico. In this entry, he mentions that in Puebla he used sampling grids to search for intensive

habitation areas. The high phosphate values were interpreted as the place for fire spot, trash pits, and burials. After excavating the detected areas, he found habitational remains.

In Chalcatzingo, Morelos, the main goal of the project was to detect the most intensive occupation areas of the site, the relationship with the surroundings, and the function of different parts of the site. In that case, the fieldwork used pits within transects to define the site extension and intensive occupation areas.

Most of these results had bad diffusion and were almost unknown. The only paper, published by *Vínculos* in 1975, had a resume of the first two experiences of phosphate studies in Mexico, but no figures were included. It was a shame because these two field experiences were the first successful applications of phosphate analysis in Mesoamerican archaeology.

Some years later, other applications of this new technique were made in the Laboratorio de Prospección Arqueológica, using phosphates as an archaeological prospection tool to look for settlement limits and garbage dispersion. Despite of some success in the delimitation of archaeological sites in Terremote, Tlaltenco, DF, in 1978, I considered that the time investment was not in accord with the information obtained (Barba 1980).

It was during fieldwork carried out in Xochipala, Guerrero, in 1978 that something changed. In prospection, we used to work with large regular grids, taking soil samples at intersections. After analyzing the samples from one small grid, it was clear that one part of the grid presented high values of phosphate, while the other showed lower values. The most interesting thing was that after a shallow archaeological excavation in the same grid, a wall foundation was exposed exactly between the high and low phosphate values (Barba 1990).

Up to then, I was used to deal with large-scale sampling of entire sites and their interpretation, but in this case, for the first time, I was looking at differences on both sides of a wall. The excavation also showed that the exterior of the structure had higher values than the interior, suggesting the important idea that human activities produced different chemical enrichment of the same surface, inside and outside of a structure.

Previously, some authors had shown how some chemical indicators such as organic matter and nitrogen were related to human activities. In order to test these ideas and the relationship with phosphates, I proposed a project to sample the earthen floor of the house of a family who was living in a small town in Tlaxcala, Mexico. The idea was to also observe their daily activities in order to correlate this information with the results from the samples. We spent some days making a floor plan of the house and taking almost 40 floor samples, as well as pictures and notes of their everyday activities.

The hypothesis to test was that the activities we observed would produce differential chemical enrichment of the floor in both sides of the walls. After some days of lab work, spot test results were mapped on the house plan. The distribution of phosphates was explained according to different activities. Also interesting, during the phosphate analytical procedure, we applied Eidt's acid solution, which produced an effervescent reaction in many samples. That reaction was the first approach to the establishment of carbonate determination; it was also plotted and by the first time showed a very interesting correlation with human activities.

That was the beginning of an important change in the use of phosphate analysis and chemical indicators. In those days, it was generally thought that these chemical techniques could detect human settlements, even going to the extreme of supposing they could detect structures. With the arrival of geophysical techniques to archaeology during the 1970s, it was soon realized that these techniques were the best approach for the detection of architectural remains, and chemical techniques were more or less put aside. Our lab, nevertheless, proposed that the chemical techniques could be even more useful for archaeology in detecting areas of human activity in floors within architectural structures. With this new approach, a major change occurred in both the scale and goals of the study of chemical residues not in soils but in floors.

During the first stages of the study of chemical residues in the floors of living spaces, it was very difficult to accept that human activities could leave such a permanent track and that residues found in the present could be related to materials used in the past. It was difficult to support because we were dealing with intangible and invisible substances that were impossible to see after excavation, and it was unbelievable that after hundreds of years, organic residues were in floors against our personal experience that these substances are lost just after some weeks.

Nevertheless, the ethnoarchaeological studies carried out showed that chemical enrichment patterns found in floors of traditional households remained some months and years and had direct relationship with activities and substances spilled on floors. Then, the main problem was to go back on time and demonstrate that organic residues could survive hundreds and even thousands of years.

Fortunately, during this time, the first results of organic residues found in Mediterranean ceramic pots came out. In some cases, those pots had inscriptions or marks describing the ancient content, and that information was useful to contrast the chemical analysis results that showed the presence of organic residues. This fact allowed to build the bridge that connected the activities carried out hundreds of years ago and the organic residues found in the pores of ceramic pots in the present. This important coincidence provided the support to accept that organic residues could survive and also be present in the pores of the floors.

In this way, the crazy idea of recognizing activity areas through the chemical study of floors was transformed in a reasonable idea that perhaps could be improved including another kind of analytical techniques. In the 1980s, the ICP was included to study chemical residues in floors (Middleton and Price 1996).

In the same way that centuries ago the Galileo's telescope and the observation of the Moon surface produced the optical theory to support it, in our field of study, the presence of chemical residues in floor is no longer questioned thanks to the discovery of the residues in pottery pores. Now the discussion could be on the appropriate analytical technique, the smallest portion of sample to be analyzed, the original substances that can be identified after the time transformation of residues, etc., but the existence of organic residues is presently a commonly accepted knowledge.

Some of the most comprehensive reviews of papers published in this field are the articles published by Holliday and Gartner (2007) and Wells and Moreno (2010), the first emphasizing phosphorous chemistry and analytical techniques while the second more concerning on the applications to archaeology in Mesoamerica.

Key Issues

Theoretical Background

The detailed analyses of archaeological materials, as well as their spatial associations, are very powerful tools for studying activity areas. An activity area has been usually defined as the association of raw materials, products, artifacts, and chemical residues accumulated in specific places as a consequence of human activities. As a part of complementary information for the study of activity areas, there are chemical indicators that can be analyzed to determine the kind of activity that was carried out on the floors (Pepe et al. 1989).

The use of chemical indicators for the study of activity areas is based on the following assumptions:

1. When an activity takes place, some liquid residues could be spilled on the floor, and, sometimes, depending on the characteristics (porosity) of this surface, the residues could be absorbed. For that reason, a differential enrichment of the floor could be observed depending on the distribution and diversity of the activities made in a room or household.
2. Once the chemical compounds, which were the by-products of human activities, have been incorporated into the floor's pores mainly as solutions, they remain protected and preserved by this matrix.
3. Through the chemical analyses of floor samples, it is possible to identify and evaluate the

presence and the spatial distribution of several indicators. Some of the floors were used for specific activities, so through their characterization, it could be possible to identify the function of the studied area.

4. The comparative study of materials and substances in any particular case, as well as previous studies in modern households, offers the possibility of improving interpretation in archaeological terms.

The differential chemical enrichment of floors is related to the type of activity (production, use-consume, storage, or waste); the periodicity, the intensity, and the duration of the activity; the changes in the spatial distribution of the activity; and the different uses of the area (in the same and later times).

For these studies, the assumption that the original floor had a homogeneous composition at the moment of its construction is required; this means that the floor composition is the same in every point of its surface; thus, the human activities modify such homogeneity by adding specific chemical residues.

Several types of floor can be recognized in Mesoamerica. From this variety, the lime-plastered floors are the most suitable for the study of activity areas because their production process with fire discards the chemical residues possibly incorporated before the use of this material as a floor (Barba 2007).

Ethnoarchaeological Approach

The ethnoarchaeological approach has been one of the ways to achieve the interpretation of results regarding the distribution of chemical residues in archaeological terms. To correlate the origin of a chemical concentration of any compound found in a floor with any kind of activity that has taken place, we can draw upon the study of the activities carried out in an inhabited domestic structure. In this respect, several interesting essays have been carried out as part of the research project on activity areas at the Archaeological Prospection Lab, with the main goal of establishing the general enrichment patterns for various activities, whether they are domestic, productive, or ritual.

As the first part of this general project in 1978, we used the phosphate analysis in a house at San Vicente Xiloxochitla, Tlaxcala, Mexico. We related direct observations, the information provided by the inhabitants with a traditional way of life, and the concentration of chemical residues in the floors of the residential unit. Among the outstanding conclusions, we found that there was a strong evidence of distribution patterns directly associated with observed activities, where the resting areas (around and under the beds) were found to be poor in phosphates, while food consumption areas and open yards were very rich in this compound. Moreover, intensive transit areas suffered considerable erosion, being, therefore, poor in phosphate content. Finally, the area where meals were prepared and cooked (where the hearth was located) was low in phosphate content but high in pH values. Some years later, the same floor samples of this house were studied again, this time including a new set of inorganic and organic tests (Barba and Ortiz 1992).

As a second stage of the same project, we made a research in the recently abandoned village of Osumacinta Viejo, Chiapas. We studied two houses, one located downtown and the other in the outskirts of the village. Both had been abandoned for 3 years. We arrived to the following conclusions: the area close to the hearth where meals were eaten presented high phosphate concentrations, while the corners and the spaces close to walls showed a considerable depletion of this compound. The places where hearths and fireplaces had been located showed high pH values. Two large concentrations of chemical elements were visualized in the areas outside the rooms. In order to explain them, the authors resorted to ethnoarchaeological explanations. For instance, the calcium distribution pattern is explained as a result of the use of lime to soften kernels for nixtamal, and, on the other hand, iron concentration was due to the treatment of agave leaves.

A more recent study of a household at Muxucuxcab, Yucatan, provided information concerning the distribution of chemical compounds in a modern house that reflects the activities of the inhabitants. Additional information was obtained interviewing the people living there

and including the results of the detailed archaeological excavation. The joint interpretation of these three levels of information clearly delimited four activity areas at the household. The same samples were studied years later to compare results from different analytical techniques (Middleton et al. 2010).

After the study of ethnoarchaeological cases, it has been proved that chemical residues existed in floors, that their distribution was not random, and that it depended on activities performed by the inhabitants. Some differences in the use of the spaces can be observed, and many of the activities produced recognizable patterns.

It was important to accumulate information from ethnoarchaeological cases in order to understand patterns in the use of domestic spaces. The study of modern and recently abandoned houses has made possible to apply the recognized patterns to the study of archaeological house floors.

The importance of the lime-plastered floors is enhanced by the fact that limestone is not readily available in the Basin of Mexico, so the lime used, firstly at Teotihuacan and later at Tenochtitlan, had to be transported from limestone outcrops close to present Tula city, among others places (Barba et al. 2009). Pre-Hispanic lime plaster was a very important technological development. Floors were very homogeneous and had a very low content of residues, since, in order to prepare the lime, limestone was fired at temperatures of up to 800 °C, thereby removing all organic materials. During the slaking and preparation with water, masons produced homogeneous mixtures that were evenly applied to floor surfaces. Once the floor was dry, it was used and began to accumulate residues in the pores as a consequence of the inhabitants' activities. After Teotihuacan, many other settlements used this kind of floors providing the opportunity to investigate the past everyday living to the present archaeologists.

Analytical Techniques

In the case of our laboratory, most of the tests selected are characterized by the ease of application; all of them are simple, reliable, semiquantitative tests, and they allow the immediate processing of numerous samples at a minimum cost and time (Barba 2007). The first set of tests carried out included phosphate, carbonate, and Munsell color determination, along with pH measurement. In addition, calcium and iron were sometimes analyzed to determine their distribution in residential areas. In all cases, the experiments have shown that variations in concentration reflect human activities. Tests for organic compounds have been incorporated in later times. It has been shown that organic compounds remain in the pores of floors as well as in the pores of ceramics. Spot tests for fatty acids, carbohydrates, and protein residues have been successfully used to study floors. Since most human activities are related to organic solutions, the study of both kinds of chemical compounds (organic and inorganic) has enriched the interpretation substantially.

Samples are usually obtained by drilling at grid intersections and collecting in plastic bags the produced powder. Sampling density is an important factor of the study. The most common density is one sample per square meter. In some cases, such as in the interior of small roofed rooms, the density can be increased to four samples per square meter, but in large open areas, it might decrease to one sample per 4 or 16 m^2. As a result, it is quite common to have hundreds and even thousands of samples for the study of a single household or residential unit. This kind of studies requires the use of low-cost and easy spot tests. For the interpretation of human activities through chemical analysis of residues in floors, it is important to look for enrichment patterns that are only revealed by large numbers of analyzed samples.

In all cases, a map of isoconcentration lines is produced showing the distribution of chemical residues in the floor under study. Whenever available, this distribution should be related to the archaeological materials found on top of the floors during excavation. In the course of fieldwork, the immediately processed analytical results sometimes have enabled researchers to modify their sampling strategy.

Gas Chromatography–Mass Spectrometry Analysis (GC-MS)

As discussed above, spot tests inform about the distribution of residues but cannot provide information on the origin of the organic residues, often constituted by complex mixtures. Frequently, it is advisable to identify each component of these mixtures, and, for this purpose, gas chromatography

coupled with mass spectrometry (GC-MS) is one of the most suitable techniques. This analytical technique allows the separation and identification of many substances, lipids in particular. This permits the interpretation of the residues absorbed in the pores of archaeological floors and ceramics, through the identification of specific markers that are characteristics of the different substances (Evershed et al. 2005).

For example, it is possible now to distinguish between animal and vegetal fats. In many cases, it has been possible to identify olive oil. Furthermore, GC-MS has allowed the identification of markers characteristic of other vegetal substances common in the European ancient diet such as wine (Guash-Jané et al. 2004) and *Brassicaceae*, a common vegetable (Charters et al. 1997). The presence of animal stables and latrines can also be detected by monitoring the presence of *coprostanol* (Bull et al. 2003; Evershed et al. 2005).

The advantages of GC-MS are therefore evident, and they are particularly related to the possibilities of knowing the specific substances involved in ancient activities. On the other side, the main disadvantage of this kind of chemical analysis consists mainly in the complex and expensive instrumentation required. Considering procedures often carried out to extract different compounds (Mottram et al. 1999), in many cases it can be an extremely time-consuming technique.

As mentioned before, the study of the distribution of organic residues in archaeological floors requires the analyses of hundreds of samples, and, probably for this reason, no case studies exist of this kind of study performed only by GC-MS analysis.

At the National University of Mexico and the University of Siena, integrated analysis of spot tests and GC-MS has been applied in order to understand the horizontal residue distribution and function of different areas or structures by spot test and then verified by the identification of some specific substances by GC-MS (Pecci 2009; Middleton et al. 2010).

Induced Coupled Plasma–Optical Emission Spectrometry Analysis (ICP-OES)

Another approach to study archaeological floors and the function of archaeological structures is the use of ICP-OES analysis of an acid extract of floor samples. This technique has been particularly useful in the identification of anthropogenic chemical elements present in archaeological surfaces (Middleton et al. 2005). It entails the characterization of a suite of elements that includes both anthropogenic and geochemical indicators, therefore making it possible to distinguish between anthropogenic and natural processes in the composition of the archaeological surfaces. A variety of extraction techniques can be used, ranging from a buffered neutral extraction to a total digestion. The particular technique employed in a given case depends on the purpose and goals of the study.

The advantage of this technique is that it is highly sensitive to subtle differences in the chemical composition of floor samples, making it possible to distinguish between a wide range of by-products involved in human activities and to distinguish between human activities and geochemical processes. The copious quantitative data produced by this technique readily lend themselves to powerful inferential statistical analysis. Factor analysis of principal components and numerical classification recognize patterns of covariance in the enrichment and depletion of elemental concentrations in the data that help to identify the patterns of activity that took place upon the surface. Both the raw data and the derivative statistics, such as factor scores, can be surface plotted to provide a visual aid for the interpretation of enrichment patterns. Both the distribution of the factor scores and the raw elemental data often mirror the areas of most intense activity and reflect activities such as food preparation, washing, or the contribution of human metabolic by-products in the soil. Because data can range over several orders of magnitude, data are usually converted to a logarithmic scale for analysis and plotting (Middleton and Price 1996).

Although a powerful technique, there are limitations to this approach, particularly in comparison to spot tests in the field. Foremost, the length of time involved in sample preparation and extraction would bar this approach for use in the field in most cases, whereas spot tests can provide immediate results in the field, which can be used to guide excavation and interpretation. A second and significant drawback is the cost of the instrument. However, beyond the instrument cost, ICP-

OES analysis of samples is fairly economical. Finally, although sensitive to some constituents of organic matter such as phosphorus, ICP-OES analysis cannot identify organic compounds.

Current Debates

One of the latest technologies developed for fieldwork that shows a broad field of applications, including archaeology, is the portable X-ray fluorescence. Recent electronic developments have provided compact instruments, with high sensitivity and at a reasonable cost. Besides many other applications in industry, environment, and conservation, in the particular case of archaeology, this kind of instruments might contribute to the advancement of chemistry applications to archaeology mainly because this analytic technique does not require sample preparation, which is a problem with previously mentioned techniques.

As many of the analytical techniques XRF determines elements. But since most of the human activities in the past are related with organic residues composed by C, N, H, and O, the challenge is to build a bridge between elementary distribution and the chemical residues produced by human activities.

Nowadays, a lot of sophisticated analytical techniques are available; depending on research goals and economic resources, all of them can be successfully applied to the study of chemical residues in floors. However, no matter which analytical tool is used, whether the most technologically sophisticated or the simplest one, it is important to bear in mind the necessity of building a bridge between the concentration of chemical residues in floors and the human activities that produced them, through the study of living households by means of observation or with controlled laboratory experiments. By not doing so, we could end up with a long list of chemical elements, even in parts per billion, with no archaeological meaning.

International Perspectives

After 30 years promoting the use of spot test in archaeology, interesting attempts have been done to establish these analytical procedures in different places. The successful ones have been done by universities. The first successful experiences were carried out in Cuba, at Universidad de la Habana and in Costa Rica. In more recent times, these ideas have been spread out in some other countries. One of these cases is the recent study of the residential units in the Aburrá region in Colombia, to figure out the domestic and productive activities of the ancient inhabitants. A special case is Italy, where Pecci at the University of Siena has been intensively working in the application of spot test to archaeological contexts of different temporalities in the Mediterranean area in addition to the use of GC-MS for the identification of residues in ceramic vessels and floors (Pecci 2009). United States has various groups that have developed different analytical approaches for the study of human activities in the past. The group in Madison, University of Wisconsin, has a long-term successful application of ICP for the study of residues in floors that began with Middleton's Ph.D. dissertation. The group in BYU has been using spot test, phosphate quantitative determinations, and ICP for the study of Mayan archaeological sites and associated market places (Terry et al. 2004). The group in the University of South Florida has been performing different experiments to understand residue behavior in the archaeological context and studying different sites (Wells et al. 2000). Very recent is the establishment of the Chemistry Laboratory in the Universidad Autónoma de Yucatán that began the study of historic and archaeological floors in the Maya region using spot tests.

Future Directions

Besides the ongoing development of the pXRF equipment for the study of elements associated to human activities, either in soil samples as a chemical prospecting tool or in floors as a tool to detect residues produced by human activities, there is a new analytical tool with promising perspectives in the detection of organic residues: the new portable infrared spectroscopy equipment. For many years, this technology has provided reliable information analyzing organic residues in laboratories, but

now it is possible to use portable equipment for the detection of organic residues in floor samples, even during the fieldwork.

A little behind is the development of new portable RAMAN spectroscopy that, theoretically, is able to detect organic residues, but this technology needs some time to reach the reliability of the infrared technology. Nevertheless, these technologies represent an open field of research to discover and need a lot of work to become useful for archaeology.

Florence Charter on Historic Gardens (1982)

Patricia M. O'Donnell
Heritage Landscapes LLC, Preservation Landscape Architects and Planners, Charlotte, VT, USA

Introduction

The 1982 ICOMOS Florence Charter on Historic Gardens (Florence Charter) was developed at a meeting of the members of the ICOMOS IFLA International Committee for Historic Gardens (now known as the ICOMOS IFLA International Scientific Committee on Cultural Landscapes) in Florence on 21 May 1981. The Florence Charter, a document addressing a specific field of garden preservation within preservation of historic resources, was registered by the International Council on Monuments and Sites (ICOMOS) as an addendum to the Venice Charter on 15 December 1982. The drafting and acceptance of this charter as an addition to guiding documents in the preservation of cultural heritage signaled an enlargement of the realm of preservation from consideration of significant architecture and monuments to include historic gardens and parks in a range of sizes, which may be associated with a building or a property important for a significant landscape. The Florence Charter ushered in the landscape as a realm for research, planning, and action in cultural heritage preservation that has progressed and enlarged in 40 years since its registration.

Definition

The Florence Charter is a document approved by ICOMOS in 1982 that defines historic gardens as "an architectural and horticultural composition of interest to the public from the historical and artistic point of view" (ICOMOS Florence Charter: Article 1). This charter specifically addresses the conservation of gardens, parks, and commemorative landscapes purposely designed and constructed of organic and inorganic materials. Historic garden maintenance, conservation, restoration, reconstruction, use, legal protection, and administrative stewardship are specifically outlined in this charter. The charter provides a clear capture of the realm of historic gardens identifying the composition of the historic garden as (1982, Article 4, The Florence Charter):

- Its plan and its topography
- Its vegetation, including species, proportions, color schemes, spacing, and respective heights
- Its structural and decorative features
- Its water, running or still, reflecting the sky

Further, the charter refers to the setting for the historic garden, beyond the garden boundaries, indicating that "The historic garden must be preserved in appropriate surroundings. Any alteration of the physical environment which will endanger the ecological equilibrium must be prohibited" (1982, Article 4, The Florence Charter). This inclusion of setting heralded the contemporary definition of buffer zones for protection of heritage resources. The Florence Charter is a touchstone to which professional practice in the realm of historic gardens and cultural landscapes constantly refers to as a foundational document framing international guidance.

Key Issues/Current Debates/Future Directions/Examples

Leadership by René Pechère, Landscape Architect

The Committee on Historic Gardens and Sites, the precursor to today's ICOMOS IFLA Cultural

Landscape International Scientific Committee, brought together a group of professionals interested in historic gardens. The committee first convened at Fontainebleau in 1971 under the leadership of René Pechère, a prominent professional with many notable private and public commissions. Pechère served as the president of the International Federation of Landscape Architects (IFLA) from 1956 to 1958 and became active again a decade later, taking charge of forming and fostering a section on historic gardens. Landscapes of historical significance were not popular topics at the time. Pechère spoke to his colleagues to convince them to support formation of this committee, saying: "Nothing starts from nothing, and it is on your past, on what you are now, that everything that you will be depends" (Pechère 2011). He defended the formation of an IFLA Committee on Historic Gardens and Sites n this way, and his leadership led to the formation of the committee in 1968 at Sardinia. In the years following, Pechère worked first with Gerda Gollwitzer, editor of "Garden and Landscape," and then brought together a garden history research team extending beyond the landscape architecture profession to include "art historians, architects, botanists, and archaeologists" (Pechère 2011). He engaged ICOMOS president Piero Gazzolo in the garden history effort, which yielded the first meeting of the committee in 1971 in Fontainebleau. Pechère assembled a talented and experienced team to work on this committee, founded on a decade of effort. At Florence in 1981, he led the drafting of the Florence Charter, which ICOMOS approved in 1982.

From Historic Gardens to Cultural Landscapes and Issues for the Future

The ICOMOS (International Charter for the Conservation and Restoration of Monuments and Sites) of 1964 (Venice Charter) is the forbearer of the Florence Charter and addresses monuments of civilization, citing architectural works within their urban or rural setting that bear witness to a civilization, cultural development, or historical event. The Venice Charter focused on the conservation of monuments as works of art and historical evidence, but failed to explicitly direct such attention to gardens or landscapes. In fact, the words "landscape" and "garden" do not appear in the Venice Charter. The Florence Charter, framed 18 years later, sought to enlarge the consideration of shared global heritage from monument and site to designed landscape. This step opened a preservation direction toward the landscape as cultural heritage worthy of conservation, an expanding understanding that continues to enlarge through the present day.

The Florence Charter of 1982 was a signal call to include garden and landscape works created with purposeful designs as heritage worthy of conservation and preservation alongside historically important monuments and sites. The concept of cultural landscapes as expressions of outstanding universal value was intensely debated through the 1980s. The entire Lake District of Great Britain was proposed for World Heritage listing during these years and denied. Cultural landscapes were added to the World Heritage Operational Guidelines in 1992 and defined as defined landscape, designed and created intentionally; organically evolved landscape, either relict or fossil where the evolutionary process is ended, or continuing evolved landscape where contemporary society is present and evolution continues; and associative cultural landscape, which have inspired art and literature, which are places of religious or spiritual beliefs or embody traditions and intangible aspects of cultural heritage (UNESCO 2012).

The 20 years from 1992 to 2012 have seen an increasing interest in and evolution of the recognition and protection of cultural landscape resources. Based on recent research, the World Heritage inscriptions of cultural landscapes in the past two decades number 98 inscribed properties, representing, in only 20 years, 10% (10%) of total inscriptions (O'Donnell et al. 2012). The following distribution of types shows:

- 7 clearly defined
- 32 organically evolved – relict
- 73 organically evolved – continuing
- 25 associative

This distribution shows the prevalence of organically evolved continuing landscapes,

which represent some 75% of the 98 inscribed cultural landscape properties. This predominance also underscores the pivotal issues in retaining authenticity of the cultural landscape heritage: managing change while evolution continues. The threats to the integrity of cultural landscapes are varied and broadly include population growth pressures, socioeconomic transformation, climate change, and human conflict with examples of urban sprawl, migration, poverty, extractive industries, modern infrastructure, civil war, and natural disasters affecting valued cultural landscapes inscribed on the World Heritage list. This range of pressures also threatens cultural landscapes of national, regional, and local significance.

Inscribed cultural landscapes represent a global range throughout the UNESCO world regions. The dispersion of properties is listed with increasing counts top to bottom as:

- 3 in the Arab States
- 10 in Africa
- 15 in Latin America and the Caribbean
- 21 in Asia and the Pacific
- 43 in Europe and North America

Thirty (30) of these inscribed properties are historic urban landscapes, where global urban populations coalesce in greater numbers. In November 2011, UNESCO approved the UNESCO Historic Urban Landscape Recommendation (HUL), which positions urban cultural heritage broadly for the first time within considerations of quality of life, economic vitality, development, industry, tourism, and evolution of urban centers. This holistic view sees heritage as a co-contributor to urban vitality in the twenty-first century. Sparked by out-of-scale development proposed adjacent to the core of historic Vienna, HUL is directed toward all urban places, each unique and each a place of heritage, enlarging the notions of the historic center or urban ensemble to include the broad urban context and larger setting (Fig. 1).

Cultural landscapes of urban areas, defined as the combined work of humanity and nature, generally comprise about half of the settlement space and contribute significantly to the character of the place. Buildings represent the other half and contribute, as a whole, to the scale, density, and character of the townscape. The public and private historic urban landscape expresses traditions and values, both tangible and intangible, forming an accreted record of interactions between people and place and rooting culture in landscape. The historic urban landscape and the urban cultural landscape offer parallel terminology for the same resources. HUL and urban cultural landscape both address the entire townscape ensemble of structures and landscapes, views, hills, slopes, vegetation, shorelines, rivers, parks, streets, bridges, walls, residences, commercial buildings, transit stops and tracks, and so forth. These urban features are composed, by humanity and nature over time, to establish the urban character. The contemporary threats to the protection of urban heritage and to fostering its vitality into the future are myriad. HUL is a vehicle both for capturing and directing a reinforcement of traditional values of monument heritage and for framing and applying a wider framework for sustaining contemporary

Florence Charter on Historic Gardens (1982), Fig. 1 Vienna panorama (O'Donnell & May 2005)

and future urban heritage values. It encourages stewardship by diverse urban actors in a collaborative, iterative process. HUL signals a scale shift that embraces historic urban cores and the territory around them, urban and rural. This evolution of foundational concepts imbedded in the Florence Charter demonstrates over 30 years a transition from precious garden and parks to cityscape and townscape, where gardens and parks are elements within a continuous urban context, all of which has heritage value and intangible and tangible heritage resources.

Another cultural landscape relevant evolution within cultural heritage preservation activity is the emergence of cultural routes and regional itineraries of large areas or multiple sites. Recognizing linear corridors of heritage value, such as the Silk Routes of ancient trade of transboundary resources and the 150 km Quebrada de Humahuaca that follows the line of the Inca Route, Argentina, among others, captures the heritage of corridor landscapes marked by human transportation and settlement uses. While the Agave Landscape and Ancient Industrial Facilities of Tequila, Mexico, a site of nearly 35,000 ha, the five regional sites of the Ifugao province Rice Terraces of the Philippine Cordilleras, the tentative listed Cape Winelands Cultural Landscape of South Africa, and many other agricultural landscapes bring forward regions that embrace long traditions of farming, crop production, and related settlements as integrated land-based cultural resources (Fig. 2).

The recognition of large-scale heritage corridors and regional itineraries embraces landscapes of place and humanity, living and evolving or relict, where archeological resources abound.

There are 91 cultural landscapes inscribed as World Heritage cultural property and 7 as mixed properties. This small group of mixed properties, which are recognized for both outstanding cultural and natural resources, opens another avenue for consideration. In cultural landscapes, we find the intersection of humanity and nature. At a 2004 US ICOMOS Symposium, a declaration on heritage landscapes, which embody cultural and natural resources, was prepared that captures a pressing issue in the realm of cultural landscapes and the future of human society: "There is a convergence of natural and cultural values in the landscape, and a growing recognition that the traditional separation of nature and culture is a hindrance to protection, and is no longer sustainable. Further, heritage landscape protection is required at the local, national and global levels in order to transmit these universally valuable heritage resources to future generations. . . With this declaration, we call for increased commitment to the gamut of preservation and conservation planning and management efforts to preserve the universally significant heritage landscapes of our

Florence Charter on Historic Gardens (1982), Fig. 2 Ifugao Rice Terraces, Philippines (O'Donnell, Nov 2012)

planet" (2004, US ICOMOS, Natchitoches Declaration on Heritage Landscapes). One of the core challenges of the current day is for humanity to embrace a positive relationship with landscape in all its forms. As stated in the World Heritage Operational Guidelines, "Cultural landscapes often reflect specific techniques of sustainable land use, considering the characteristics and limits of the natural environment they are established in, and a specific spiritual relation to nature. Protection of cultural landscapes can contribute to modern techniques of sustainable land use and can maintain or enhance natural values in the landscape. The continued existence of traditional forms of land use supports biological diversity in many regions of the world" (UNESCO 2012: 98, item 9). Cultural landscapes we live in, enjoy, and learn from each day are significant cultural resources expressing historic human endeavor and the qualities of place with import for tomorrow. By addressing the cultural value of gardens as the combined works of humanity and nature, the Florence Charter began the steps on the path we tread today. Cultural landscapes are heritage resources at the junction of our global future.

Folklore Archaeology

Ceri Houlbrook
University of Hertfordshire, Hatfield, UK

Introduction

It is not hyperbolic to state that folklore, in its myriad forms, is a feature of all societies, regardless of time and place. As such it has been the subject of countless studies from various disciplines, of which Archaeology may seem one of the least obvious; such phenomena as "traditional" beliefs, customs, and legends may not seem obviously archaeological because they do not appear, at first glance, enmeshed in material culture. That first glance, however, is misleading.

To take a subcategory of folklore as an example, beliefs in preternatural forces – from the benevolent to the malevolent – lead to a desire to

control those forces. This desire to control engenders customs: habitual practices enacted by believers with the design to harness the good (heal the sick, attract luck, fulfill a wish, etc.) or to divert the bad (counter a witch's curse, placate spirits, deter demons, etc.). These customs tend to involve some form of physical activity and engagement with the material world – e.g., the deposition of an object – and are thus bound up in place, action, and thing. Folklore Archaeology is concerned with said place, action, and thing; it is the study of how folkloric beliefs, customs, and legends exist within the material record.

Folklore Archaeology, while still not formally recognized as a discipline, is a field of research which many folklorists – and some archaeologists – have been engaging with throughout much of the twentieth century. Some researchers have engaged this area in more depth than others, and some more successfully, but generally speaking their approaches can be divided into two primary, although not mutually exclusive, strands (Gazin-Schwartz 2011):

1. The Folklore of Archaeology: The study of folklore concerning archaeological sites and artifacts, which were not initially created or employed in connection with the customs, beliefs, and legends later applied to them. This approach can prove problematic where the researcher seeks to identify folklore as the "survivals" of prehistoric beliefs and rituals but can be highly enlightening where folklore is viewed as one of many layers of meaning attached to a site or artifact.
2. The Archaeology of Folklore: The archaeological analysis of artifacts, monuments, and landscapes created and/or employed in connection with customs, beliefs, and legends. This approach is primarily concerned with how folklore manifests itself in the material record and utilizes both archaeological techniques in the contextualization of obscure practices (e.g., what can this artifact tell us about how and why it was used?) and folkloric methodologies in the analysis of obscure material remains (e.g., what can oral sources tell us about the function of such an object?)

Definition

Folklore Archaeology is a subdiscipline of both Folklore and Archaeology, referring to the areas of intersection between the two. Given the context of this entry, a definition of the latter is not required; the former, however, requires significant unpicking. Capitalized "Folklore" designates the discipline, which is concerned with the study of (noncapitalized) "folklore" as a subject matter. This is a problematic term as there has been, and continues to be, debate surrounding its meaning (see Further Reading). Its earliest definition comes from 1846 when British writer William Thoms penned a letter to *The Athenaeum*, a literary magazine published in London, suggesting an alternative to "what we in England designate as Popular Antiquities, or Popular Literature"; he recommended, instead, "a good Saxon compound, Folklore, – *the Lore of the People*."

Since the term was coined, it has been subjected to criticism, contestation, and re-definition, in large part due to the ambiguity of its two primary components: "lore" and "people." Taking the latter component first, what constitutes "the People"? Early definitions clearly identify the "folk" as the rural, uneducated, lower classes of society. However, few folklorists today adhere to these rather narrow-minded – and condescending – specifications. Rurality is no longer seen as a prerequisite of the "folk" and it is generally agreed that any group of people, regardless of class or education, can constitute "folk," so long as they have a sense of collective identity, normally borne from a shared common factor. This can be geographic location, language, religion, occupation, or hobby, to name only some.

"Folklife" (Swedish *folkliv*), therefore, is the anthropological study of the culture of a group of people sharing a sense of collective identity; it is, simply put, the folks' way of life: their practices, architecture, clothing, art, etc. What, then, is folk*lore*? It can be viewed as a subcategory of folklife, but there is some debate over where (or, indeed, if) the line is drawn between the two terms. Many folklorists define "lore" as a list of genres (beliefs, legends, customs, etc.) while simultaneously acknowledging the reductive nature of this

approach. It is generally recognized today that no single definition of "lore" will suffice and that what is encapsulated by this term varies depending upon context and the folklorist her/himself. However, broadly speaking, the "lore" of "folklore" is information known by, and disseminated amongst, a group of people, as it refers to customs, beliefs, and legends.

Folklore is not usually considered to be in accordance with widely accepted or authoritatively established theological doctrines, although it is not necessarily exclusive of/to them. What largely distinguishes "folklore" from orthodox rituals and religions is its mode of transmission. It is information passed from person to person, usually without any formal indoctrination and most certainly without any authoritative text (e.g., the Bible, the Qur'an); instead, it is information transmitted orally. Orality is therefore considered central to folklore. However, changes in modes of communication – most notably the Internet – have led to alterations in definitions (see below).

Folklore as a discipline is the study of the above and utilizes largely ethnographic methodologies, but also some textual sources where relevant, in the collection and analysis of a group's folklore. The British *Folklore Society* (considered in more detail below) states on their website that they are concerned with "all aspects of folklore and tradition," including the compilation and interpretation of the following:

> ballads, folktales, fairy tales, myths, legends, traditional song and dance, folk plays, games, seasonal events, calendar customs, childlore and children's folklore, folk arts and crafts, popular belief, folk religion, material culture, vernacular language, sayings, proverbs and nursery rhymes, folk medicine, plantlore and weather lore. (The Folklore Society 2013–2018)

Folklore Archaeology is the archaeological study of all of the above. It is the employment of methodologies from any subdiscipline of Archaeology – e.g., material culture studies, phenomenology, contemporary archaeology – in the analysis of the material manifestations of folklore: artifacts, monuments, and landscapes connected with customs, beliefs, and legends.

Historical Background

A history of Folklore on a global scale is beyond the scope of this entry; geographic focus will, by necessity, be narrowed down and will rest largely, although not exclusively, on Britain (but see International Perspectives). However, attention must first be given to Europe more broadly, which witnessed a heightened interest in folklore studies during the nineteenth century. German scholars Jacob and Wilhelm Grimm are well known for having vigorously collected and published folklore, to be greatly popularized in later media, and other nineteenth-century folklore collectors included Kaarle Krohn of Finland, Paul Sébillot of France, and Giuseppe Pitrè of Italy, to name only some. Forging links with these early pioneers of Folklore, England's *Folk-Lore Society* was founded in 1878, and it was throughout the Victorian period when the famous names of Folklore – Andrew Lang, Joseph Jacobs, George Laurence Gomme, Alfred Nutt, Edwin Sidney Hartland, Edward Clodd, and William Alexander Clouston – were at their most active, publishing numerous books and papers on the subject.

However, even during the Victorian period, Folklore was not considered an academic discipline. The above folklorists were, without exception, private scholars: lawyers, publishers, civil servants, and businessmen, with no university affiliations (Dorson 1976). And during the early twentieth century, as scholarship became more of an academic profession than the pastimes of Victorian amateurs, the "golden age" of Folklore reached its end. Unlike Anthropology and Archaeology, Folklore had not gained academic acceptance as a discipline in itself with the rise of universities in Britain, and it was either subsumed by other disciplines – History, Literature, Anthropology – or discarded entirely.

Prior to this, Folklore and Archaeology had been practically inseparable. The pre-Victorian British antiquarians rarely distinguished between the collecting of material relics and the recording of ancient practices and beliefs. However, by the mid-nineteenth century, both Folklore and Archaeology had made their move away from antiquarianism – and from each other, with

Archaeology and Folklore beginning to view themselves as separate and distinct professional fields. This academic divorce appears to have been initiated by those identifying themselves as archaeologists, who – with Britain's first serious excavations beginning in the late eighteenth and early nineteenth centuries – had begun embracing scientific techniques and empirical practices. The nineteenth century, therefore, saw the emergence of the newly styled archaeologists, who sought to dissociate themselves from Folklore most likely because (unlike Archaeology, and as outlined above) it had not received academic acceptance (Gazin-Schwartz and Holtorf 1999: 9).

It is posited that archaeologists rejected folklore, viewing its value with skepticism, because of its questionable authenticity and accuracy; often finding that folk tradition and material remains did not correlate, they opted to dismiss the former as inauthentic (Gazin-Schwartz and Holtorf 1999: 5). Folklore was slightly less dismissive of Archaeology, but from the outset of its development as a separate field in the nineteenth century, it was clear that material culture was not considered central to the study of folklore. Tellingly, in its first publication in 1878, the *Folk-Lore Society* defined its objectives as "the preservation and publication of Popular Traditions, Legendary Ballads, Local Proverbial Sayings, Superstitions, and Old Customs" (Folklore Society 1878, cited in Gazin-Schwartz and Holtorf 1999: 22), with no reference at all to material culture. And by the mid-twentieth century, most folklorists (although not all, see below) had become more concerned with the collection and preservation of oral traditions than with the study of artifacts.

This model is far from global (see International Perspectives) and far from absolute. For example, the broader study of folklife is heavily associated with material culture and has been for some time (see Glassie 1999; George 2010). Explicit association between Archaeology and the more specific Folklore, however, is rarer – but not absent. There has been some engagement with both disciplines, as is evident by the inclusion of "material culture" in the long inventory of subjects listed on the *Folklore Society* website (see above). And this engagement has resulted in two primary strands of research: the Folklore of Archaeology and the Archaeology of Folklore.

The Folklore of Archaeology

For much of the twentieth century, studies of the relationship between Archaeology and Folklore in Britain have taken one main form: the collection of folklore concerning archaeological sites, usually compiled by folklorists with an interest in archaeology. The general consensus among these scholars was that folklore constituted the remnants – the "survivals" – of prehistoric beliefs and rituals; thus, folklore was utilized as a resource to contextualize the material evidence, most often a prehistoric monument.

Walter Johnson was one of Britain's first folklorists to apply this theory to the archaeological record in 1908. In his book, *Folk-Memory; or the Continuity of British Archaeology* (1908), he traced folkloric associations and uses of megaliths back chronologically in order to contextualize them, considering, for example, the healing powers attributed to prehistoric holed stones. Johnson was not, however, under any illusion of direct continuity; while he wrote of the endurance of veneration at certain megaliths, from prehistory to the nineteenth century, he warned his readers that most traditions will have been "grossly perverted" (1908: 132), stating that any "folk-memory" must be "scrupulously tested" (1908: 319).

Similar methodologies are employed by later scholars, who draw on folklore as a contextualizing resource for the understanding of prehistoric monuments, from Stonehenge (Fleure 1948) to the many "countless" megalithic stones (Menefee 1975). Likewise, Bord and Bord, writing in the 1970s, refer to "race-memory" as the "only real illumination" onto the significance of the prehistoric sites of the British Isles: standing stones, henges, hill-forts, and burial mounds (1976).

In most cases, a degree of skepticism is maintained concerning the continuity of these folk traditions; they are not presented as unaltered survivals from prehistory but as distorted remnants which, if very carefully interpreted, may

yield some truth over the monuments' original purposes. The details of a tradition will undoubtedly have changed over the centuries, but traditions reflect attitudes, and attitudes are more likely to have been consistently inherited: a site is considered sacred today because it was considered sacred 3000 years ago (Bord and Bord 1976: 1–2). Not all scholars, however, accepted these theories of long-term unbroken continuity; Grinsell (1976), for example, was a little more skeptical.

Grinsell is probably the most widely known scholar of the folklore of British prehistoric sites and, unlike the majority of scholars considered in this entry, Grinsell classifies himself as an archaeologist rather than as a folklorist (1976: 9). It is probably his archaeological background that made him more wary of drawing on the oral traditions associated with prehistoric sites in order to contextualize them. Although he offers little in the way of interpretation – the majority of *Folklore of Prehistoric Sites in Britain* (1976), for example, is a simple county-by-county catalogue of prehistoric sites with folkloric associations – he does acknowledge that many associated traditions are far more recent in origin than they seem, and he is discerning in his distinction between the older remnants (folklore) and the more recent traditions ("fakelore").

The Archaeology of Folklore

The other strand of Folklore Archaeology is the analysis of material manifestations of folklore. This can be subdivided into two further strands: (1) the use of known customs, beliefs, and legends in order to contextualize otherwise obscure material evidence and (2) the use of material evidence in order to contextualize otherwise obscure customs, beliefs, and legends. The former is evident in studies from the mid-twentieth century to the present day, with examples of obscure material evidence including foundation sacrifices, ritual markings on domestic timber, witch-bottles, "thunderstones" and "thunder-axes," and concealed garments (Swann 1996; Eastop 2006), to name only some.

It was Ralph Merrifield, however, whose book, *The Archaeology of Ritual and Magic* (1987), was the first full-length volume devoted to the materiality of British folkloric customs and beliefs. Attesting that, as ritual and magic were, in many cases, aspects of everyday life, they should leave as many traces in the archaeological record as any basic human activity, Merrifield seeks to identify and catalogue them (1987: 1). Covering a wide chronological period from the pre-Roman Iron Age to the twentieth century, with a geographic focus on Europe – most prominently south-eastern England – he reconstructs ritual activity, such as the deposition of witch-bottles and mummified cats, from the archaeological evidence, supplementing it wherever possible with written sources.

In other scholarship on the subject, folklore is not employed to elucidate the archaeological evidence, but vice versa. For many British folkloric customs, there are few – if any – relevant contemporaneous literary sources; oral testimonies and the material remains are thus the only surviving testaments to the custom and subsequently the only contextualizing resources available. Concealed objects are particularly pertinent to this. These are objects, ranging from shoes to mummified cats, which are discovered in unusual locations within buildings (e.g., in the roof space, within the walls, up the chimneybreast). No literary evidence has come to light explaining why such objects were concealed. However, by analyzing the archaeological evidence – considering both the physical attributes and symbolic associations of such objects – researchers have reconstructed the beliefs and ritual activities which may have led to the deposition of concealed objects (Davies and Houlbrook Forthcoming; Eastop 2006; Hoggard 2004; Houlbrook 2013; Hukantaival 2016; Massey 2014; Swann 1996).

Other seemingly enigmatic material finds have been subject to similar analyses: burn marks, for example. Lloyd et al. (2001) have only a few vague literary references to the apotropaic powers of candles to contextualize the flame-shaped burn marks found on late-medieval/early-modern domestic timber. They thus employ the material evidence of the burn marks themselves in order to

"decode" the custom. Employing experimental archaeology to determine how the burn marks were produced, they ascertain what materials and conditions would have been required to produce such marks and conclude that they were probably intended as apotropaic devices. Their study demonstrates the successful application of experimental archaeology to the interpretation of enigmatic – and often ignored – material evidence.

Key Issues

The current key issue in Folklore Archaeology is the legitimacy of the term itself. This entry is being penned in England, where Folklore is currently considered largely marginal. Despite being at the forefront of folklore collection in the nineteenth century, today England boasts no professional body of folklorists, bar the *Folklore Society*. This society, founded in 1878 and still in existence today, has an estimated 375 members and three journal issues of *Folklore* published annually. However, it is not a government- or university-funded organization; registered as a charity and run by volunteers, it demonstrates the passion and commitment of its members rather than a countrywide and well-established academic interest in the subject. Indeed, only a handful of universities in Britain provide courses in Folklore, with most of these in Scotland (the University of Aberdeen and the University of Glasgow). At the time of writing, the only English university with an established specialism in Folklore is the University of Chichester, which accommodates the "Sussex Centre for Folklore, Fairy Tales and Fantasy" (although see below).

Scholars and organizations alike have chosen to avoid the term "folklore" or discard it altogether; the "Survey of Language and Folklore" founded at Sheffield in 1964 became the "Centre for English Cultural Tradition and Language" in 1974, while the "Welsh Folk Museum" in Cardiff, founded in 1948, was changed to "St Fagan's National History Museum." Academic avoidance of the term "Folklore" may stem from its pejorative connotations, whereby the "folk" were identified as the less-educated, lower classes of society. It may also stem from the perceived "quaintness" of the term, with scholars preferring to employ alternatives, such as "ritual" or "popular beliefs."

The twenty-first century, however, has witnessed a perceptible shift in attitudes towards both the term "Folklore" and its suitability as a focus of research. The seminal work of Gazin-Schwartz and Holtorf (1999) and Gazin-Schwartz (2011) has undoubtedly contributed to this, drawing scholars' attention to the advantageous pairing of Archaeology and Folklore, a pairing which was re-ignited in 2011 with the introduction of University College London's Institute of Archaeology's "Popular Antiquities: Folklore and Archaeology" conference, co-organized by the *Folklore Society*. This, and its subsequent conference in 2012, attracted scholars from across the globe, demonstrating the widely-felt benefits of utilizing both resources in scholarly research and in fostering a dialogue between the two disciplines. The 2010s also witnessed the introduction of the *Folklore Society*'s "Newer Researchers" conference, held in collaboration with the Elphinstone Institute, Aberdeen (2014, 2015, 2017), providing a platform for folklorists to not only share their research, but to legitimize their self-identifications as folklorists.

Other promising changes are afoot, with a Folklore Studies MA currently being set up at the University of Hertfordshire, led by Owen Davies and due to open in 2019. Additionally in 2018 the Centre for Contemporary Legend was launched by a special interest research group based in the Cultural Communication and Computing Research Institute at Sheffield Hallam University, including David Clarke, Diane Rodgers, and Andrew Robinson. The long term aim of the Centre is to create an institutional base with an archive and teaching program that could act as a focal point for those working in the field of folklore and legend studies in the UK. There have also been recent calls to implement a national survey of contemporary folklore in England, with John Widdowson (2016) penning an article in *Folklore* which considers the benefits and challenges of such an endeavor. This proposal has

been met with enthusiasm and further suggestions (cf. Young 2018).

Two other key issues go further in legitimizing "Folklore Archaeology." Firstly, the recognition that the folklore of archaeology (e.g., prehistoric sites) should not be harnessed in an attempt to elucidate origins. Instead, it can be used to ascertain how a monument or landscape has been perceived and utilized throughout history into the present day. Stonehenge is the most obvious example: the contemporary and early modern folklore surrounding this structure undoubtedly sheds little – or no – light on its original purpose but reveals much about how prehistoric structures can serve as focal points within communities. Archaeology and folklore are two distinct, opposing forces; folklore surrounds a prehistoric site despite – and often in contradiction to – the archaeological evidence, and while archaeology can provide factual history, folklore offers largely metaphorical history (Voss 1987: 81). While the archaeologist may seek facts, the folklorist seeks explanation.

Another key issue is the acknowledgment of the redundancy of the term "authenticity." "Folklore," synonymous with the term "tradition," is often perceived as fixed and immutable; however, many customs, beliefs, and legends are in fact the result of recent adaptation or invention (Hobsbawm and Ranger 1983). This is sometimes a conscious and deliberate process, producing "fakelore" (Dorson 1976), i.e., inauthentic folklore. Recent scholarship, however, recognizes that there is no such thing as "inauthentic folklore." Folklore is transient and changeable. Its orality causes malleability – in fact, it necessitates it. Like any other entity, folklore must adapt in order to survive; therefore, while there is a theoretical original for any custom, belief, or legend, there is no "authentic" or "inauthentic" version, just as there is no "accurate" or "inaccurate" account. This is not to say that the adaptations, recontextualizations, and inventions of folklore should be taken as given, but that they are worthy of careful study in and of themselves.

An interdisciplinary dialogue between Archaeology and Folklore is thus a dialogue between two different systems of meaning; archaeology (which seeks facts) and folklore (which seeks explanations) are not partial fragments of the same whole, correlated, and combined to reveal a full picture. They are two different modes of representing the past, often providing contradictory accounts of events, landscapes, and artifacts (Gazin-Schwartz and Holtorf 1999). It is, therefore, generally recognized that an archaeologist's employment of folklore should not be to seek factual answers which supplement the material evidence, but to aid in an understanding of the malleability of artifacts, monuments, and landscapes, and the multiplicity of meanings attributed to them. Folklore is not (usually) meant to be taken literally; it is primarily symbolic and therefore should not be resorted to in the search for facts, but in the search for meaning.

International Perspectives

No university worldwide officially recognizes Folklore Archaeology as a discipline or subdiscipline. Some global regions, however, have a notably deeper academic acceptance of Folklore itself. In the Scandinavian countries, for example, folklore studies have a particularly long history; Sweden can trace academic interest in folklore back to the seventeenth century, and in Finland, the early eighteenth century. However, it was the nineteenth century that saw a rise in scholarship on the subject, with the founding of such establishments as the Nordiska Museum in Stockholm and the outdoor museum in Skansen. In 1898, Kaarle Krohn of Helsinki University became Professor of Finnish and Comparative Folklore, and subsequently the first person in the world to hold such a chair.

Ireland likewise has a rich history of folklore collecting, with the establishment of the Irish Folklore Commission in 1935, leading to the National Folklore Collection at University College Dublin, now listed on the UNESCO Memory of the World Register. Key figures in this highly successful commission included Seán Ó Súilleabháin and Åke Campbell, both of whom were heavily influenced by Sweden's model of folklore collecting. Today, two of Ireland's

universities (University College Dublin and University College Cork) offer specialisms in Folklore.

In North America, on the other hand, Folklore has emerged as an academic subject relatively recently, having originally been taught in universities as an aspect of Literary Studies. Francis James Child, Professor of English, began his work on British folk ballads at Harvard in the 1850s, and although there were no formal courses in Folklore at this time, the subject was incorporated into Literature and Philology courses. In the late-nineteenth and early-twentieth centuries, Child's successor, George Lyman Kittredge, widened Harvard's English department's folkloric focus to include tales, beliefs, and proverbs, while anthropologist Franz Boas was beginning his collection of North American folklore at Clark University, Massachusetts.

Because of the influence of these early folklorists, most Folklore courses in America are taught in departments of Anthropology and English. However, it was specifically the growth of American Studies in the 1930s and 1940s which maintained academic interest in American folklore. It was in 1940 when the first MA degree and doctoral minor in Folklore was offered, at the University of North Carolina, followed by its introduction as a doctoral program at Indiana University in 1949, which was later elevated to departmental status by Richard Dorson. By the 1980s, at least 509 American and 19 Canadian universities offered courses in folklore.

Additionally, many Folklore departments and centers have been founded relatively recently, demonstrating that these programs are not simply survivals from the subject's earlier popularity. For example, official Folklore degrees first began to be offered at the University of Oregon in 1989, and the Center for Folklore Studies at the Ohio State University was established in 1995. However, in the majority of cases, Folklore is paired with another subject: Mythology, Ethnomusicology, Oral Traditions, Cultural Studies, Folklife, Popular Culture, Anthropology, Ethnology, Literature, and Art. Significantly it is not paired with Archaeology, demonstrating that even in environments where Folklore has retained (or is receiving recent) relative popularity, Folklore Archaeology is still not formally acknowledged as a distinct field of research.

Future Directions

As folklore is recognized as a malleable, dynamic phenomenon, frequently adapting to time and place, techniques in its study require equal malleability and dynamism. As such, Folklore Archaeology must adapt its approaches and methodologies in response to contemporary issues. For example, one future direction for the discipline involves a continuation of the question: who constitutes the "folk" and what therefore constitutes "folklore"?

This is a question that has occupied folklorists since the advent of the discipline but is particularly pertinent today given the rapid changes of contemporary society. Previously, folklore has been defined as customs, beliefs, and legends communicated orally amongst a group of people. However, the Internet, and the consequent advent of rapid, geographically unbound communication, has altered how – and amongst whom – customs, beliefs, and legends are transmitted (Blank 2009). The Internet enables a global discourse; cultural identity is no longer necessarily equated with geography and therefore a "folk group" has no need for a geographical base. A person can be sitting at their computer transmitting folklore to/from/about a different county, country, or continent – a county, country, or continent they may never have been to. This has deep implications for Folklore Archaeology in that it alters how people – the "folk" – engage with artifacts, monuments, and landscapes, which in turn influences the customs, beliefs, and legends they subsequently apply to them.

Folklore Archaeology must also engage further with – and has much to offer – the subject of migration. Valuable work is currently being undertaken, for example, on what light the archaeological record can shed on the migration of folk ritual practices. Research has uncovered significant material evidence of British and European "domestic magic" (e.g., concealed objects,

charms, graffiti) in the USA and Australia (Evans 2010; Manning 2012; Augé 2013; Burke et al. 2016), with 2017–2018 seeing the first intensive folklore archaeological survey in Australia (Evans 2018). More work needs to be undertaken to compile the data from the various continents into one large-scale accessible resource, which would allow for comparisons and contrasts of the material evidence to be made. The Concealed and Revealed Project, based at the University of Hertfordshire, is currently managing a crowd-sourced website, with the aim of producing such an international resource (https://www.historypin.org/en/person/66740).

Current Folklore research is also concerned with assessing the historical evidence along with the archaeology, testing the limitations for understanding the material against the historical and folkloric archival evidence. Davies and Houlbrook's (Forthcoming) work contextualizing such phenomena as concealed mummified cats, horse skulls buried beneath floors, and witch balls, for instance, demonstrates the necessity of drawing on historical literary material as well as on the physical evidence. Such research reveals that we can be led astray by adopting the methodologies of Archaeology at the expense of History, and future work will hopefully combine both disciplines with that of Folklore.

Much work still needs to be done on promoting acceptance of Folklore Archaeology as a field of research. However, a widespread interest in the materiality of customs, beliefs, and legends has recently surfaced, with three edited volumes so concerned published within a year of each other (Boschung and Bremmer 2015; Houlbrook and Armitage 2015; Hutton 2015). The volumes' contributors, hailing from a wide variety of disciplines, focus on the material evidence of folkloric practices, demonstrating not only growing acceptance of, and interest in, a dialogue between Folklore and Archaeology, but also the widely felt benefits of it. Folklorists and archaeologists alike can contemplate the approaches taken in these volumes and perhaps consider alternative angles to their research, thus promoting further successful interdisciplinary dialogues.

Folorunso, Caleb Adebayo

Kola Adekola
Department of Archaeology and Anthropology, University of Ibadan, Ibadan, Nigeria

Basic Biographical Information

Seasoned university Administrator and Academic, Caleb Adebayo Folorunso (Fig. 1) was born on 13 April 1956. He attended Oyan Grammar School for his secondary education and the famous Igbobi College for his Higher School Certificate. He graduated from the then Department of Archaeology, in 1979, with a Bachelor of Arts honors degree with Second Class Upper Division Certificate. He completed his masters in the same department in 1981 before proceeding to the Universite Paris I Pantheon-Sorbonne in France for his doctorate degree program which was successfully defended in 1989. Caleb Folorunso also has a certificate in African archaeology from the Universite Libre de Bruxelles, Belgium, under the Erasmus program in 1989.

Major Accomplishments

Professor Folorunso's contributions to African archaeology centered on four main themes, ethno-archaeology, historical archaeology, cultural resources management, and archaeology and tourism. He has written over 30 journal articles and has contributed more than 20 chapters in books. His contribution has not been limited to teaching and research as he has supervised over 15 master's degree dissertations and 6 Ph.D. theses. Three of his doctoral students are now professors in universities in Nigeria, while the rest are also occupying research positions in the universities. He is a mentor to a crop of young brilliant Nigerian archaeologists and budding archaeologists spread over universities across the world. He had been involved in international collaborative research works with scholars from

Fig. 1

University of Cambridge (UK), University of the Witswaterand (South Africa), and Kenyan National Museum in the African Farming Network Project.

Professor Folorunso served as Head of Department of Archaeology and Anthropology for 10 years, 1995–1997, 2002, and 2005–2010. His tenure witnessed tremendous infrastructural growth coupled with a strong support for the department by the university authority in terms of equipment and facilities. The scholar is the immediate chairman of University of Ibadan Senior Staff Housing Committee, a member of the Senate, and a member of Appointments and Promotions Panel in the University of Ibadan since 1993.

Adebayo Folorunso is one of the most visible African archaeologists based on the continent. He was elected the Vice President of the World Archaeological Congress in 2008 at WAC 6 in Dublin Ireland and retired in 2013 at WAC 7 in Jordan. Before then he was for a decade the Senior Representative of WAC for the West African Region. For his invaluable contributions to the organization, Folorunso was given a life membership award of WAC since 2004. His selfless service and exemplary contributions to the World Archaeological Congress at several levels was duly recognized with the WAC President's Award at the 8th World Archaeological Congress Meeting in Japan in August 2016. Other distinctions include General Secretary, West African Archaeological Association, 1994–1996; Business Manager, West African Journal of Archaeology, 1989–1999; and a member of the advisory board Nigeria Heritage, a journal of the National Commission for Museums and Monuments. He is a member of several editorial boards including *Archaeologies*, a journal of the World Archaeological Congress; Journal of the Environment and Culture; and *Journal of African Diaspora Archaeology and Heritage*. He became a Fellow of the Archaeological Association of Nigeria in August 2016.

Foodways in Historical Archaeology

Eric Tourigny
History, Classics and Archaeology,
Newcastle University,
Newcastle upon Tyne, UK

Introduction

Foodways represents a conceptual approach adopted by researchers to study the social, cultural, and ideological meanings associated with food. Adoption of this concept allows archaeologists to broaden their research questions, progressing away from simple dietary reconstructions to explore the human behaviors associated with food and the role(s) food played in shaping individual and group identities. The concept was widely adopted in historical archaeology (understood here as the archaeology of the post-CE-1500 period). Historical foodways was an especially prominent research theme in the United States from the 1970s onward. It has since been used to address a variety of archaeological research questions in North America and beyond. The following discusses the definition and adoption of the concept in historical archaeology while summarizing key research developments.

Definition

Concepts akin to that of foodways and how it is used today were introduced in anthropology by Audrey Richards in the 1930s (Richards 1932) and further popularized through the works of Margaret Mead and the National Research Council of the United States between 1942 and 1945 (e.g., Mead 1943; NRC 1945). While addressing the challenges involved in studying food-related behaviors, these early works were influential in emphasizing the links between food habits (e.g., the procurement, preparation, and consumption of food) and expressions of culture. The first archaeological publication referencing the term was James Deetz's highly influential book *In Small Things Forgotten*, which presented research linking food habits to material culture (Deetz 1977). The book included a definition of foodways taken from folklorist Jay Anderson (1971) which now likely represents the most cited definition in American historical archaeology. It describes foodways as "the whole interrelated system of food conceptualization, procurement, distribution, preservation, preparation, and consumption shared by all members of a particular group" (Anderson 1971: 2). Later archaeologists add to this definition the behaviors relating to the disposal of food waste.

A variety of data sources are used by archaeologists to investigate past foodways. Analyses of plant and animal remains, cooking wares, food processing tools and equipment, architecture, landscapes, and skeletal remains and historical documents, among other sources of evidence, can be revealing of the foods that were (and were not) eaten, the modes of production and preparation, differential consumption practices, discard habits, nutrition, divisions of labor, and many other food-related habits. Each type of data also carries their own limitations and inherent biases (e.g., differential preservation or deposition patterns). Representing such a complex cultural system, no single type of data can be used to entirely reconstruct past foodways, and the most comprehensive studies manage to incorporate data from diverse types of evidence.

Specific use of the term "foodways" is most often employed by historical archaeologists working in the United States, a reflection of the strong influence of Deetz's work on subsequent research. However, the conceptual links between food and culture, whether or not the term "foodways" is used, were adopted globally by archaeologists working on historical or other time periods. Over the past two decades, the concept is increasingly being employed as a theoretical paradigm guiding archaeological research in Canada, Europe, and Oceania. These studies do not always identify Deetz or Richards as etiological influences and may cite later anthropological, sociological, or archaeological sources; however, all share in the idea that food and food-related habits are cultural constructs imbued with meaning.

In Britain and Ireland, archaeological research making use of a foodways paradigm tended to focus on earlier periods of history (e.g., prehistoric, Roman, medieval), while later postmedieval assemblages were often deemed unimportant, uninformative, and, therefore, unworthy of collection by excavators working in the commercial archaeology industry (Murphy 2007: 371). Thomas (2009) called attention to the lack of postmedieval research making use of animal bones specifically, and more archaeologists are now working to address this issue. Unfavorable views of the historical period are changing as more people are engaging with postmedieval archaeology through organizations like the Society for Post-Medieval Archaeology and an increasing number of excavation reports are describing postmedieval assemblages, leading to more data available for foodways-related research.

Key Developments

Upon adoption of the concept, many historical archaeologists focused on describing the foodways of early colonial groups settling in the United States and the Caribbean. Their research was highly influenced by the New Archaeology movement and its emphasis on identifying links between subsistence strategies and environmental adaptations. Reitz and Cumbaa's (1983) study compared pre- and post-contact diets between Spanish and Native American groups in Florida. Their approach and conclusions emphasized adaptive and acculturative interpretations of early Spanish colonists' foodways. Deetz's (1977) study of eighteenth-century ceramics in the northeast United States led to his identification of a shift in the foodways and broader world views of Euro-Americans at the time. He noticed ceramics became more common, specialized, and individualized and noted that meat was prepared for individual portions as opposed to being served as larger portions for groups of people. His structuralist interpretations of these data in combination with other observations led him to describe a change in mind-set within the culture: from an earlier disorganized, organic, and corporate world view toward a mechanic, ordered, and individual one. Over the following decade, landmark studies concerning the foodways of earlier Americans continued to emphasize the adapted foodways of colonists to their New World setting. The influence of interactions with non-Europeans in the development of colonist foodways was rarely acknowledged, and the ever-changing nature of food habits over the long-term process of colonialism was generally underexplored.

The 1980s saw historical archaeologists becoming increasingly interested in research themes exploring socioeconomic relationships. Foodways archaeology was no exception, and many studies were concerned with identifying socioeconomic status through the analysis of differential consumption patterns of food-related material culture or plant and animal remains. Schulz and Gust (1983) represent one landmark study whereby the authors compared nineteenth-century cattle bone assemblages originating from deposits of contrasting socioeconomic standing. The purpose was to later associate economic values to specific cuts of beef and use animal bones to identify socioeconomic differences within archaeological materials. Many others followed similar approaches, often interpreting foodways through the lens of capitalism and consumer choice theory (e.g., various papers in Spencer-Wood (1987) and Schmitt and Zeier (1993)).

Scholars increasingly broadened the interpretive scope of foodways throughout the late 1980s and early 1990s. Research emphasized the flexible nature of foodways and the roles these played in the formation of individual and group identities. Similar approaches continue today, recognizing that food habits and cultural identities are inextricably linked and under constant renegotiation as a response to changing internal and external pressures (Twiss 2012). Status, gender, ethnicity, religion, and other social phenomena are increasingly explored vis-à-vis their role in shaping foodways. Researchers continued to consider the effects of environment, market availability, consumer choice, and socioeconomic status but discussed these alongside social phenomena while considering the effects of intercultural interaction.

Archaeologists became especially interested in studying the foodways of subaltern, silenced, or disenfranchised groups (e.g., slaves, indigenous populations, ethnic minorities, women, and children), and interpretations of their foodways were no longer being framed as consequential to the actions of colonists or oppressors but as active and reciprocal relationships between cultural groups. In the case of African American and indigenous populations, researchers have used foodways as evidence for the maintenance of a distinct cultural identity where groups and individuals were actively engaged in sociopolitical interactions while also using foodways as a form of cultural resistance and social cohesion (e.g., Franklin 2001; Cipolla et al. 2007). Studies of gendered foodways highlight the fluid dynamics of concept by demonstrating changing meanings ascribed to material culture over time and the shifting status of women (e.g., Yentsch 1991).

As we approach the present, themes that were previously discussed on broader scales of analyses are increasingly being explored at a local or regional level, highlighting variations in the practice of foodways among people of similar culture/ethnicity/social status that are occupying comparable but distinct regions. While cities, surrounding regions, and rural areas did not exist in isolation, their populations each experienced their own unique sets of challenges, circumstances, and histories leading to different identities and ways of interacting with the world around them. Archaeological research examining the foodways of individual regions is generally focused on exploring the local conditions that lead to unique cuisines and food habits while describing the role of food in expressing and maintaining local or regional identities. Such focus allows archaeologists to explore the subtle nuances of regional foodways and the effects of multiple social phenomena without being limited to investigating one single theme or cultural group.

Future Directions

Food plays such an integral role in the daily lives of all people, and its centrality as a research theme is unlikely to waver as foodways research is becoming increasingly global. A rising number of archaeological excavations and improved field methods are continuously producing valuable data. Sophisticated laboratory technologies (e.g., stable isotope and residue analyses) are allowing archaeologists to extract new types of previously unimagined data and address exciting new research questions. When combined with advances in data sharing and management, researchers increasingly have access to large, complex datasets allowing them to further delve into the complexities of foodways and explore sections of society that have traditionally been more elusive in the archaeological record. As more projects are conducted at the regional/local level, the eventual combination of their data has the potential to address broader anthropological themes such as colonialism and expressions of identity (Peres 2017). The challenge will be to reconcile large and varied datasets while also better integrating and promoting our work outside of the discipline. Foodways research is truly multidisciplinary with studies conducted in fields as diverse as English studies to public health and epidemiology. Unfortunately, archaeologists are mostly working and publishing within their own discipline, while the opportunity exists to embark on truly interdisciplinary research with wide-ranging impact.

Foraging to Farming Transition: Global Health Impacts, Trends, and Variation

Clark Spencer Larsen
Department of Anthropology, The Ohio State University, Columbus, OH, USA

Introduction

Among the most important developments in the history of our species was the transition from a dietary focus based exclusively on hunting, gathering, and collecting wild plants and animals to a diet based in whole or in part on domesticated plants and animals (Gremillion 2011). This development is especially profound because it laid the foundation for the world we live in today, including the rise of complex societies, urbanization, dramatic population increase, and establishing conditions for the appearance and spread of various infectious diseases (sometimes as epidemics), decline in nutritional quality, increase in interpopulation conflict, and the appearance of a plethora of other health and well-being issues now present and anticipated for the foreseeable future.

The transition to farming and domestication generally is all the more remarkable when one considers that the shift took place in just the last 10,000 or so years of the 6–7 million years that humans and humanlike ancestors have been inhabiting the planet. The shift to farming began some 10–12 thousand years ago by a few human groups in the Middle East. By 5,000 years ago or so, dependence on domesticated plants had developed in at least 10 primary centers in both the Old World and the New World and had begun to spread from these centers around the globe. Today, all of humanity is dependent to some degree on domesticated plants and animals for food. In this discussion, the human impacts of the foraging to farming transition – especially with regard to consequences for health and lifestyle – are highlighted using the study of human remains recovered from archaeological contexts.

Key Issues/Current Debates/Future Directions/Examples

There has long been a scientific interest in health outcomes in past human populations, especially with regard to the origin and history of specific diseases, such as leprosy, syphilis, and tuberculosis (Buikstra et al. 2012). For much of the history of paleopathology – the study of ancient diseases – the interest in this topic has been largely in diagnosis in either individual skeletons or limited collections of skeletons from archaeological localities. Today, the prevailing focus has been in documenting and interpreting health outcomes based on the study of collections of remains from localities and regions in order to understand population variation in health. It is this population orientation coupled with broad-based temporal and spatial comparative analysis of series of human remains that has helped to open up new perspectives about the history of health and well-being (Ortner 2003). These kinds of investigations have been crucial in developing a more informed understanding of etiology of disease and health conditions. In part, bioarchaeologists strive to understand health for addressing issues relating to major adaptive transitions, such as those associated with dietary change, settlement pattern shifts, and alterations in living circumstances generally. The foraging to farming transition is probably the most comprehensively investigated issue addressed by bioarchaeologists, in part because it reveals some common patterns globally. On the other hand, it has also revealed considerable variation in health and well-being that is likely related to highly localized circumstances and conditions.

In the 1970s and 1980s, a small group of biological anthropologists recognized the fund of data that the study of human remains could provide for drawing a better understanding of the foraging to farming transition, especially with regard to assessment of health as a measure of adaptive success (or failure). For example, in a number of settings in North America, authorities reported increased prevalence of pathological conditions, reduced stature, and other indicators, reflecting poorer health and elevated stress in later farming populations compared to earlier foragers or incipient farmers (e.g., see Stout 1978; Goodman et al. 1980; Larsen 1982; Cook 1984; Rose et al. 1984). Similarly, other early studies revealed evidence of impacts of food and food preparation technology on masticatory function and craniofacial morphology (e.g., Carlson and Van Gerven 1979). These investigations provided the basis for the development of the general hypothesis that the shift from a lifeway based on foraging to farming occasioned a worldwide decline in health and quality of life.

The early studies stimulated the further investigation of the costs and consequence of the foraging to farming transition (and other forms of economic intensification) in settings around the world. These investigations of various indicators of health and lifestyle (Table 1) reveal some common trends in comparison of earlier foragers and later farmers in a range of settings worldwide (Cohen and Armelagos 1984; Larsen 1995, 2003; Cohen and Crane-Kramer 2007; Mummert et al. 2011). This record is dominated by the generally better context for and study of larger samples of skeletons in North America than in most other areas of the world. In view of the North American record, a number of key trends emerge that are repeated in some (but not all) settings in other continents where archaeological human remains have been studied. Indeed, the scientific literature for these continents is far more comprehensive now than it was just 10 years, especially in Asia (e.g., Domett 2001; Oxenham and Tayles 2006; Perry 2012; Pechenkina and Oxenham 2013; Temple and Larsen 2013). Nevertheless, skeletal samples are either nonexistent or poorly studied for large regions of South America, Europe, Asia, and Africa (and see discussions by various authors in Steckel and Rose 2002; Cohen and Crane-Kramer 2007). Viewed collectively, however, the record shows a picture of increasing morbidity, poorer health, and generally deteriorating conditions and quality of life as human populations became increasingly dedicated to farming.

What do we now know about human impacts in relation to the transition from foraging to farming and its biological impact? Health outcomes

Foraging to Farming Transition: Global Health Impacts, Trends, and Variation, Table 1 Skeletal variables used to characterize health and lifestyle in archaeological contexts[a]

Variable	Cause/condition
Health	
Dental caries	Carbohydrate consumption (sugars, starches)
Periodontal disease	Poor oral hygiene in carbohydrate-rich diet
Antemortem tooth loss	Periodontal disease, dental caries
Enamel hypoplasia	General physiological stress under poor living conditions
Enamel microdefects	General physiological stress under poor living conditions
Dental asymmetry	General physiological stress under poor living conditions
Tooth size	General physiological stress under poor living conditions
Growth rates	General physiological stress under poor living conditions
Adult height	General physiological stress under poor living conditions
Cribra orbitalia and porotic hyperostosis	Iron deficiency of various causes
Periosteal reaction/ inflammation	Infection or trauma
Scurvy	Vitamin C deficiency
Rickets/osteomalacia	Vitamin D deficiency
Leprosy	Specific bacterial infection
Tuberculosis	Specific bacterial infection
Treponematosis (venereal and nonvenereal)	Specific bacterial infection
Lifestyle/activity/workload indicators	
Osteoarthritis	Repetitive loading of articular joints
Cross-sectional geometric properties	Continuous loading of limb bones involving bending/ torsion

[a]This list is not exhaustive. See Cohen and Crane-Kramer (2007), Steckel and Rose (2002), and Ortner (2003) for detailed explanation and additional variables

reflect two circumstances. First, they reflect the properties and nutritional quality of kinds of foods consumed, especially of the domesticated plants. For example, the major plants – maize, wheat, and rice – are starches. Dietary focus on starches promotes dental caries (tooth decay), periodontal disease, and oral health problems generally (Larsen 1997; Hillson 2008). Second, farming societies tend to live in more permanent, densely crowded settlements. In contrast to foragers, who tend to move on a regular basis and have low population size and density, this kind of environment promotes the maintenance and spread of infectious disease (Larsen 1997; various in Cohen and Crane-Kramer 2007). Some of the best evidence for this process is in North America where there is an impressive body of evidence to show increase in various specific and nonspecific infectious diseases and other health conditions (e.g., treponematosis, dental caries, periosteal reactions), nonspecific stress indicators (e.g., enamel hypoplasias, cribra orbitalia, porotic hyperostosis, stature), and workload/activity impacts on articular joints (osteoarthritis) and skeletal adaptation involving work and activity (cross-sectional geometric analysis of long bone morphology). Generally speaking, for example, in North America and some settings in South America, the increased focus on maize and some other plant domestics resulted in significant declines in oral health, and the associated settlement changes involved decrease in mobility substantial evidence for disease and illness.

Bioarchaeological analysis inferring level of workload and activity reveals highly variable results (Larsen and Ruff 2011), as do analyses of indicators of health and lifestyle (e.g., various authors in Cohen and Crane-Kramer 2007; Pinhasi and Stock 2011). That is, in some regions, biomechanical properties known as cross-sectional geometric properties increase (e.g., Tennessee River valley) but decrease in others (e.g., coast of the southeastern US Atlantic). In the Georgia coast, dramatic increases in osteoarthritis and skeletal robusticity following European contact suggest the intensification of farming practices (Larsen et al. 2001; Larsen and Ruff 2011). Other regions of the world show similar trends as North America and South America, especially in regard to a general deterioration in health in nearly all places where plant domesticates were adopted and consumed with some degree of dominance in diet.

The growing record of bioarchaeological data is beginning to reveal some important trends that show variation in health, with some regions displaying evidence of less dramatic changes in

health than in other regions. Presumably, the pattern of variation reflects geographic differences in the types of plants that were produced and consumed (various in Cohen and Crane-Kramer 2007). For example, in East Asian rice farmers, there is significant presence of dental caries and periodontal disease (e.g., Douglas and Pietrusewsky 2007; Temple and Larsen 2007). On the other hand, a number of Asian rice farmers have relatively low caries prevalence, especially when compared to maize farmers in the Americas. Some authorities argue that rice is less cariogenic than maize (Sakashita et al. 1997; Tayles et al. 2000; Domett 2001; Oxenham 2006; Pietrusewsky and Ikehara-Quebral 2006; Domett and Tayles 2007). In at least one setting where rice production and consumption increased, there is a significant decline in prevalence of dental caries (Domett 2001). Similarly, although diachronic comparisons of foragers and farmers show clear reduction in adult stature (an indication in reduced health), there are some exceptions showing no change or increase in stature (see Mummert et al. 2011).

The record for links between population aggregation and health outcomes in early farming societies is also highly variable. There are numerous instances of increase in cribra orbitalia and porotic hyperostosis (indicators of iron deficiency anemia) and periosteal lesions (infection) in farmers relative to earlier foragers (Larsen 1995; Cunha et al. 2007; Pechenkina et al. 2007; Klaus and Tam 2009), but the frequency of these conditions is low in a number of settings in Southeast Asia (e.g., Domett and Tayles 2007; Douglas and Pietrusewsky 2007) and Western Asia (e.g., Hillson et al. n.d.). Community health in late prehistoric populations in eastern North America was highly variable (Milner 1991). The variable pattern of infection prevalence also points to a high degree of diversity between human groups occupying very different landscapes and physiographic zones, ranging from highly fertile river bottoms to marginal uplands or coastal regions (various in Steckel and Rose 2002; Cohen and Crane-Kramer 2007).

Analysis of patterns of osteoarthritis and skeletal robusticity (cross-sectional geometry of limb bones) reveals evidence relating to workload and activity patterns in the foraging to farming transition and in populations who intensified their farming practices. Osteoarthritis presents a highly variable record, with some regional analyses revealing declines, others showing no change, and still others showing increases to varying degrees (Cohen and Armelagos 1984; Bridges 1992; Larsen 1995; Lambert 2000; Steckel and Rose 2002; Cohen and Crane-Kramer 2007; Larsen and Ruff 2011). A complementary bioarchaeological record of workload and activity is available from long bone biomechanical analysis. This record reveals a pattern of decline in skeletal robusticity. This record, however, is highly region specific reflecting variation in degree of sedentism, terrain, climate, the kinds of plants grown, and degree of commitment to domestication (see Ruff 2008, 2010; Larsen and Ruff 2011; Lieverse et al. 2011; Stock et al. 2011).

There is a decline in skeletal robusticity in Neolithic and other early farming societies compared to foragers, with some exceptions (e.g., Bridges 1989). The record also reveals, however, that intensification of farming shows a reversal of a trend for decrease in skeletal robusticity in at least one locality (Larsen and Ruff 1994). There is considerable variation in the rate and timing of decline in skeletal robusticity in comparison of the skeletons of men and women. For example, in the Nile valley, activity in women appears to have decreased later or only minimally in comparison with men (Stock et al. 2011). This pattern reflects the degree of variability in temporal and spatial patterns of sexual dimorphism in comparison of a broad range of biomechanical analyses emerging around the globe. These male–female differences in timing and pattern of skeletal robusticity are no doubt related to local circumstances and strategies of plant and animal exploitation. Most settings analyzed by bioarchaeologists reveal that while males clearly had a role to play in plant production, they were nevertheless largely responsible for hunting, sometimes involving long-distance travel, whereas females were likely responsible for tending crops and preparation of food. It seems likely, then, that women were more closely associated with the village or habitus than males.

Much of the bioarchaeological record described above represents a cost assessment of health for populations that adopted agriculture. The record of health in many places where the farming transition took place, however, seems to contradict the record emerging from paleodemographic reconstructions for the period. That is, the record of health shows one of general decline, whereas the record of demography shows one of increasing fertility and population growth – often remarkably so – during and/or following the adoption of agriculture (Sattenspiel and Harpending 1983; Buikstra et al. 1986; and see applications by Bocquet-Appel and Naji 2006; Bocquet-Appel and Bar-Yosef 2008; Bocquet-Appel 2008; Lambert 2009). A central goal of bioarchaeology is to assess the relative success of a population to maintain homeostasis under different environmental circumstances, including the foods eaten and the degree of success in acquiring them (see Lambert 2009). The skeletal indicators discussed above track the ability of a population to maintain homeostasis. The biological costs seem to be at odds with the increase in enhanced reproductive outcomes, with the latter showing indication of success, at least as it relates to survival and increased birthrates (Armelagos et al. 1991; Lambert 2009). The implication is that health should not be regarded as a prime mover for the rise of agriculture. Rather, declining health was a consequence of the increase in population and change in the kinds of foods consumed. It would seem, therefore, that humans can live in deplorable conditions involving more disease and debility, but not so much as to have a negative impact on reproductive success.

In summary, the transition from foraging to farming had clear disadvantages and advantages for our species. The remarkable increase in population in the last 10,000 years speaks to the evolutionary success of humankind. The increase in disease and morbidity reveals the health and behavioral costs of our evolutionary success. The balance of cost and success is the story of our species, a story that will likely continue for the long term.

Introduction

Methodology in the analysis of human remains varies considerably in relation to context and problem orientation. Human remains are found in a myriad of contexts, with different levels of completeness and with varying degrees of preservation. All of these factors influence approach and the types of tests that can be utilized in analysis. The central problem to be examined also shapes methodology selection.

Definition

Forensic Analysis

In forensic applications, the particular issues presented by each case largely dictate what procedures should be employed. Forensic anthropologists bring awareness of the range of approaches possible to each issue. With this perspective, they then can select the appropriate techniques to solve the problems presented by each individual case.

Methodology selection in forensic work begins with recovery. Knowledge that remains are buried within a discrete location calls for archaeological techniques that remove the surrounding soil, leaving the remains and associated evidence in situ. Thorough documentation employing photography, mapping, and note-taking is required.

If remains are known to be buried, but the exact location is unknown, remote sensing techniques may be called for. These can include ground-penetrating radar, electromagnetic testing, soil resistivity, and even manual probes. The terrain and topography can be key factors in selecting approaches. Remote sensing methods excel in rural areas with homogeneous soils and topography.

Of course, human remains can be found in many different environments and each requires thoughtful consideration of appropriate recovery techniques. Skeletonized remains located on the ground surface do not require the archaeological approaches discussed above but still call for careful documentation and removal of debris so that evidence position can be clearly ascertained. Marine environments present special challenges and may dictate use of diving equipment. Recovery in all situations demands proper documentation, packaging, and general evidence control, ensuring the integrity of the chain of custody.

Key Issues

Human Versus Nonhuman

Recognition of human remains usually can be accomplished with visual examination by a skilled practitioner. Challenges surface with fragmentation and/or evidence of extensive postmortem (taphonomic) alteration. Scanning electron microscopy/energy dispersive spectroscopy (SEM/EDS) can be useful to distinguish fragments of bone or tooth from other materials. Histological techniques examining internal structure at the microscopic level sometimes can distinguish nonhuman fragments from those of humans. Protein radioimmunoassay (pRIA) offers a procedure that can determine species of bones and teeth. The nature of the evidence, financial resources, and the medicolegal problem dictate which of the above approaches are employed.

Age at Death

The choice of methods to use in the estimation of age at death depends upon the general life stage of the individual. For neonates and very young infants (0–2 years), bone size provides the best information. If the small bones are relatively complete, measurements can be taken and utilized in regression equations to estimate body length. Chronological age can then be estimated by using appropriate population-specific data on the age correlation with body length.

For older infants, children, and adolescents, bone size can provide useful information as well, but if present, teeth represent the most accurate age predictors. Although dental eruption proffers some information, the most accurate estimates are derived from dental formation. Selection of which published dental standards to utilize depends upon the likely ancestry of the remains and the particular teeth present.

Many means exist for adult age estimation depending upon the evidence present and the general age of the individual (young or old adult). Most seasoned practitioners utilize all of the approaches that are suitable for the evidence recovered and then develop a reasoned interpretation. These applications may involve teeth as well as bones. They can include morphological assessment, measurement, and/or microscopic and radiographic techniques. Key areas of the skeleton examined include the sternal rib ends, pubic symphysis, vertebral bodies, long bone joint surfaces, teeth, auricular area of the pelvis, long bone internal structure (both microscopic and macroscopic), and cranial sutures.

Sex Estimation

Approaches to sex estimation usually involve visual examination of comparative adult morphological features, especially those on the pelvis. Metric techniques also are available including custom discriminant function equations. These morphological methods are not applicable to juvenile remains because of the minimal expression of sexual dimorphism in them.

Recently, molecular processes for sex determination have been employed as well. These approaches can determine sex in both adult and

immature remains and also in fragments that allow sufficient DNA recovery. Molecular procedures are more time-consuming and costly but offer definitive determinations in cases where sex assessment is crucial. Thus, if the pelvis is present and well preserved, morphological techniques of pelvic assessment would likely be chosen. If the pelvis is not present, size of other bones should be considered with the realization that only those extremely robust (male) or gracile (female) offer definitive information. Molecular techniques comprise the methodology of choice with fragmentary or immature remains or any situation in which accurate determination of sex is extremely critical.

Stature Estimation

Estimates of living stature can be useful in building the biological profile of a recovered skeleton. Regression equations derived from various population samples are available to aid in this process. Determining the appropriate equation to use depends upon the bones recovered and their likely ancestry. When multiple equations are possible, selection should be driven by their relative accuracy.

Ancestry Estimation

Ancestry evaluation in a forensic context can include a variety of methods such as morphological assessment of bones and teeth as well as metric discriminant function analysis. Recovered evidence and its context must influence decisions on the approach and interpretation method. Analysis of ancestry calls for an understanding of the social/historical dimensions of locally employed racial categories as well as representation/sampling issues of the metric approaches.

Time Since Death

Evaluation of time since death can include methods of morphological assessment as well as more analytical approaches. Since the extent of tissue preservation is highly variable and context dependent, objective techniques such as radiocarbon analysis can prove useful. The use of radiocarbon analysis with special attention to the modern bomb curve can distinguish ancient from modern remains. This type of analysis can even clarify the birth and death dates for individuals in some age at death and chronological categories, granted that the appropriate tissues are preserved.

Other Issues

Multiple forensic techniques are available for personal identification, assessment of pathological alterations and treatment of disease, facial imaging, taphonomic (postmortem) factors, and evidence of foul play. Like other areas of forensic application, choice of methodology depends upon the particular evidence recovered and the specific question being addressed.

Cases in forensic anthropology vary extensively in the problems they present. An unknown skeleton recovered from any context usually requires a full analysis with the general goal being construction of the biological profile of a missing person that might lead to identification. In contrast, some cases that arrive in forensic anthropology laboratories may represent previously identified individuals, but trauma analysis may be required. Some requests for examination focus specifically on such techniques as facial approximation, photographic superimposition, or identification of particular evidence.

In studying human remains from archaeological contexts, skeletal biologists employ a similar logic in methodological choice. Selection is problem oriented and shaped by the nature of the recovered evidence.

In paleopathology, proper employment of differential diagnosis techniques is critical. Microscopic and radiographic procedures frequently are utilized to assist diagnosis and interpretation. Molecular attempts to identify the residual DNA of particular pathogens represent an exciting new development with great potential to sharpen understanding of the history of disease.

Paleodemography relies extensively on the methodology of age and sex estimation outlined above in regard to forensic applications. Consideration of appropriate statistical approaches and sampling issues are key factors.

Biological distance studies rely upon varied methodology of measurement, morphological assessment, population sampling, and statistical

procedures. Recent advances in instrumentation and computer software development have enabled three-dimensional morphometric assessment providing more penetrating interpretation. Ancient DNA analysis offers a genetic approach to issues of past population relationships. Methodology assessment in this area of skeletal biology is influenced by sample preservation and availability, as well as cost factors and accessibility to appropriate equipment and facilities.

The field of biomechanics presents the opportunity for understanding patterns of human physical activity as evidenced in skeletal remains. Studies of biomechanics rely extensively on methodology in radiographic imaging and computer modeling. Such technological advances can aid in providing appropriate methodological choices in this field.

Although analyses of human skeletal remains vary greatly in the different areas of application and research, several themes are apparent. The extent of tissue preservation and context of recovery represent key factors in methodology selection. The particular problem being investigated largely determines the selection of techniques used. While many techniques are routinely employed, there is no standard protocol for all applications. Investigators must be aware of the range of possible methods available and wisely select those that are most useful for each specific application. Technology continues to advance rapidly offering skeletal biologists a growing number of choices.

Forensic Anthropology and Archaeology in Disaster Response

Eric B. Emery
National Transportation Safety Board, Washington, DC, USA

Introduction

Forensic anthropology has continued to demonstrate its usefulness to the field of disaster

response since the publication of T. Dale Stewart's *Personal Identification in Mass Disasters* (1970). Today, the increasing numbers of specialists in this area are applying their knowledge, skills, and research abilities to all aspects of disaster victim recovery and identification, personal effects management, and family assistance (Sledzik 2009).

Victims of mass disasters are often difficult to identify due to extensive trauma, fire, and other modifying forces associated with these types of incidents. Depending on the scale of the disaster, human remains may also be in advanced stages of decomposition by the time responders can extricate them from the scene, thus adding to the overall suite of identification challenges. In these circumstances, bereaved family members cannot be expected to provide reliable visual identifications of remains; instead, appropriate scientific practices must be employed.

Although the legal requirement for conducting identifications resides with the medicolegal authority in the jurisdiction where the disaster occurred, it is possible for a high-volume surge in fatalities, associated with a specific incident, to overwhelm the capabilities of these systems – particularly at smaller medical examiner or coroner's offices with limited resources. Such challenges require a multidisciplinary response that can include the assistance of forensic anthropologists experienced in disaster recovery operations, human remains and evidence processing, and the identification of individuals whose remains are severely fragmented, burned, decomposed, or otherwise unrecognizable (Kontanis and Sledzik 2008; Sledzik 2009).

Definition

Forensic anthropology plays a comprehensive role across the three critical areas of disaster response: the recovery scene, the temporary morgue, and interactions with families (Sledzik 2009). Trained in the principles and techniques of archaeology, with an extensive background in taphonomy, human osteology, and trauma analysis, anthropologists routinely work alongside medicolegal and forensic practitioners in the fields of pathology, dentistry, radiology, fingerprint analysis, and molecular biology (i.e., DNA). When requested to attend a scene, the work of an anthropologist is primarily to assist and support the medicolegal authority responsible for victim recovery, identification, death certification, and the final release of remains – all areas of critical importance to family members and to the settlement of insurance claims and estates.

Key Issues

Disaster scenes can be broadly categorized as having resulted from natural phenomena (e.g., earthquake, tsunami, tornado); an accident (e.g., vehicle collision, pipeline explosion, stadium collapse); or criminal activity (e.g., shooting, bombing). The recovery contexts that result from such events are complex, presenting commingled biological remains, personal effects, and other diagnostic evidence that can be distributed over areas ranging from meters to kilometers. These immediate challenges are only exacerbated by the compressed timeline that all medical examiners/coroners face as they attempt to balance the needs and concerns of family members and society with their overall medicolegal responsibility for victim recovery and identification, and in a "zero defect" operational environment (Dirkmaat et al. 2001; Sledzik 2009).

Victim identification begins with the recovery effort at the disaster scene. Regardless of the type of incident encountered (natural, accident, or criminal), preserving the overall integrity of the scene's spatial and temporal context is of paramount concern. Subsequently, the shared core objectives that drive investigators at any mass fatality incident are very similar: locate the scene, define its maximum dimensions, and if possible, clearly delineate and secure its boundary line; identify, number, document, and collect all physical and contextual evidence; and transfer all such evidence to the proper medicolegal authority, in a manner that does not harm its probative value or the chain-of-custody.

Appropriate strategies for search and recovery operations ensure that all areas throughout the disaster scene are surveyed and that human remains, associated personal effects, and other probative evidence are systematically detected, recorded, and collected using scientific methods and techniques. The quality of work at the recovery scene can influence the overall success of the victim identification process inside the morgue. Thoughtful practices on scene can mitigate additional disturbance of human remains and evidence by responders and the accidental loss or destruction of evidence. Subsequently, practitioners are developing and implementing more consistent operating procedures; reporting on the accuracy, repeatability, and level of estimated uncertainty; and defining the quality assurance and quality control processes employed.

Today, systematic approaches designed to maximize search coverage and effectiveness are being codified almost exclusively within the discipline of forensic anthropology. The development and validation of these standardized protocols – specifically in measures of survey completeness, precision mapping systems and technologies, and spatial data collection, visualization, and analysis – are firmly rooted in the study of geographic surfaces and field archaeology (O'Sullivan and Unwin 2003; Dirkmaat 2012). Applied science programs at institutions like Mercyhurst University, the University of Sydney, the Victorian Institute of Forensic Medicine, and Istanbul University represent just a fraction of the total number actively supporting worldwide advancements in survey methods, body documentation techniques, and recovery protocols for disaster scenes. In addition, the International Committee of the Red Cross (ICRC), the International Commission on Missing Persons (ICMP), and the international policing organization (INTERPOL) have all created guidelines for the recovery of victims from mass fatality contexts.

Among the first tasks confronting any disaster response is determining the scope of the incident and the context of the recovery scene. In order to effectively respond, the incident command structure needs to gather information (as soon as possible) about what happened, where the incident occurred, the pertinent environmental conditions, an estimated number of victims and fatalities, the potential health and safety hazards associated with the scene, and any immediate security issues. These data, in turn, help shape the planning effort and the mobilization of personnel and resources for human remains recovery and identification, personal effects management, and other evidence collection and investigation activities.

While there have been significant advances in a number of technological areas associated with disaster response, the implementation of new, higher-resolution remote sensing instruments in some contexts is one of the most useful innovations being applied during initial evaluation of recovery scenes. A reconnaissance survey, similar to the type used in archaeological fieldwork, provides a systematic and comprehensive approach for defining and securing the scene. The goal of this survey is to rapidly evaluate the scene's general size, orientation, and complexity at the earliest moment possible, in order to guide operational planning efforts and develop the most appropriate recovery strategy.

Integrating overhead imagery with data collected on the ground (during initial walkthroughs) can provide a more complete and accurate understanding of the incident area as a whole and the spatial distribution of the victim recovery scene across the landscape. In modern response work, the traditional walkthrough is being supplemented (if not preceded) by aerial reconnaissance of various kinds – e.g., vertical and oblique photography, overhead satellite imagery, and even active types of remote sensing, such as LiDAR. A key advantage shared among these techniques is the fact that they are nonintrusive, thus the potential for scene disturbance or contamination is nearly eliminated. Large-scale assessment and interpretation of damage areas, evidence and wreckage distributions, and scene accessibility is enhanced by the advent of spatial analysis and visualization software capable of layering and displaying massive amounts of remote sensing and other georeferenced data via Geographic Information Systems (GIS). These systems integrate data collected by various means, at different times, and across a range of scales (Greene 2002).

The context of a recovery scene is the basic interpretive framework used by forensic anthropologists in the field; the same concept is fundamental to medicolegal, and to some extent, accident investigations (Dirkmaat 2012). The position of and spatial relationship between human remains, personal effects, and other physical evidence is the key to understanding what happened and to reconstructing the different factors that contributed to the event.

The location of evidence and the spatial associations that exist between items of evidence contained within the scene, or between evidence and its surrounding matrix, help to create statistical models that assist with some of the more challenging disaster victim recovery tasks. Among these are models for identifying the full horizontal and vertical limits of scene boundaries, maximizing coverage of search areas, quantifying the effectiveness of various survey patterns and regimen, and interpreting scene context through spatial analysis of evidence distributions (Dirkmaat et al. 2008; Dirkmaat 2012).

As practitioners, Dirkmaat and Hochrein have, in particular, recognized that a significant number of the problems that arise in disaster scene recovery work are inherently spatial in nature; therefore, exacting methods in survey, mapping, and evidence collection, specifically adapted for use in either open or confined mass fatality scenes, can help mitigate post-incident commingling and damage of human remains and other evidence (Dirkmaat 2012). Although protecting the spatial integrity of these scenes can be difficult, it is indeed necessary. As an example, during the transition from life-safety to recovery operations, responders often have to move victims, property, and other potentially diagnostic evidence. Non-transportable, contextual data are subsequently lost, unless they can be documented.

Wind, water, and other geomorphic agents – completely apart from human activity – present some of the most dynamic forces affecting the spatial integrity of evidence at scenes. Aircraft accidents into steep, mountainous terrain have resulted in landslides capable of obscuring large portions of wreckage, as was the case with Avianca Flight 410, lost near Cucuta, Colombia, in 1988 (Levinson and Granot 2002: 80). By contrast, impact into water may involve a combination of high and low-energy transport mechanisms. These recovery scenes can become dispersed over a distance of seabed, or along the bottom of a river, into a secondary context by the movement of the water (e.g., waves, tidal currents, flow volume).

Although the interpretive value of three-dimensional spatial patterns and postdepositional formation processes has been widely understood by the geological and archaeological sciences, the same awareness is only recently gaining acceptance among medicolegal investigators, largely through their increased contact with forensic anthropologists working in medical examiner/coroner settings (Crowder et al. 2012).

Arguably one of the greatest challenges presented by mass fatality scenes is the mixing together, or "commingling," of highly fragmented human remains. Tuller et al. (2008) have begun examining ways in which spatial analysis can assist in sorting out commingled remains using statistical methods, such as the nearest neighbor criterion. Although this application of spatial analysis and statistics is relatively new, the concept has been widely employed as a presumptive starting point in forensic anthropology casework, especially for scenes with multiple individuals deposited into complex assemblages (Tuller et al. 2008).

Traditionally, the function of the forensic anthropologist in the disaster morgue centered on triage and sorting tasks, as well as the documentation of hard tissue remains (Kontanis and Sledzik 2008; Mundorff 2008). The anthropology station represents just one stop along the high-throughput morgue operation. Complete postmortem documentation follows a well-defined work progression from case admission processing and the assignment of a unique tracking number to photography, radiography, pathology, fingerprints, dental, and DNA sampling (Sledzik 2009).

A number of different evidence accountability and data management challenges must be addressed through sound quality control and assurance measures before the first set of remains

enters the morgue flow. As anthropologists have assumed greater management roles in disaster victim morgue operations over the past two decades, they have had to move beyond the limits of their forensic specialty and develop a better understanding of the effectiveness and efficiency of evidence tracking systems, the proper order of analytical stations, and what configurations best support the requirements of the broader medicolegal investigation. Redundant systems of data capture, with systematic verification checks, are also being modeled from professional survey and archaeological site work, and applied to help manage the overall quality and reliability of the documentation effort at the scene.

Effective management of the identification effort also demands a proactive role in family assistance on the part of the medicolegal authority. Anthropologists can assist with identifying the core needs of victims, family members, and their support networks; they help facilitate and coordinate the timely recovery and identification of victims and the return of personal effects; and they help explain the re-association and group remains processes to families and legal authorities. In some cases, the provision of family assistance is required by law; yet even when there is no formal requirement, local, state, and federal entities continue to provide information and guidance to the medicolegal community and to others affected by the incident.

Antemortem data collection – a critical factor in victim identification – hinges largely on contact with the families of those "unaccounted-for" individuals known to be associated with the incident. This process is complex and it requires a commitment of personnel and resources beyond the postmortem data collection effort being carried out in the morgue. Antemortem data can be influenced by several variables: the nature of the disaster (open, e.g., bomb blast in a shopping mall vs. closed, e.g., plane accident); the demographic profile of each respective decedent; and the availability, quality, and accuracy of the data (Kontanis and Sledzik 2008). Death investigators, mortuary personnel, and forensic anthropologists are among the specialists trained to conduct antemortem data collection interviews.

Positive identification of victims requires the comparison and reconciliation of antemortem and postmortem information. The threshold of certainty needed to move from a "circumstantial" to a "positive" identification, however, presents a complicated problem that medicolegal professionals confront daily. In a disaster victim context the potential for a misidentification can be magnified by the number of victims, the condition of their remains (fragmented, burned, etc.), the thoroughness of the recovery effort, the nature of the victim population (open vs. closed), the availability and quality of antemortem records, and access to DNA reference samples. Forensic anthropologists are examining likelihood ratios as a means of quantifying the strength of an identification (Steadman et al. 2006). Specifically, they are looking at the ratio between the likelihood that evidence of a unique biological characteristic (or set of characteristics) came from a particular individual, versus the likelihood that it came from a random, unrelated individual. In other words, what would be the probability of obtaining the evidence if the identification was correct versus the probability of obtaining the same evidence if the identification was incorrect? Figura (2011) has developed this concept further for its specific applications in disaster victim identification work. And recently, de Cosmo (2012) has devised a decision support tool designed to reduce subjectivity when using physical attributes to make identifications in these same types of contexts.

Future Directions

New emphasis is being placed on the use of validated scientific practices in disaster victim recovery and identification. This trend has been stimulated in part by the Supreme Court's rulings in *Daubert v. Merrell Dow Pharmaceuticals, Inc.* (1993), *Kumho Tire Company v. Carmichael* (1999), and the Rule 702 Amendment (2001). *Daubert*, in particular, has changed the rules on the admissibility of expert testimony in federal courts; expert witnesses are being required to provide an estimation of probability and to substantiate their assertions with methods that have been

scientifically tested and validated (Dirkmaat et al. 2008). The National Academy of Sciences (2009), in the USA, has further underscored the Supreme Court's concerns, specifically citing a need for standards, guidelines, and best practices in human identification techniques (National Academy of Sciences 2009).

Significant variation in medicolegal and law enforcement systems across the country has prompted the development of best practices in death investigation. Just a few years after the *Daubert* ruling, the National Institute of Justice and the National Association of Medical Examiners in the USA began pushing for standardized operating procedures and checklists in the field of death investigation and in the performance of autopsies (National Academy of Sciences 2009). Refining the focus more specifically on mass fatality management issues, forensic anthropologists and other practitioners from the medicolegal and forensic communities have voiced a similar need for guidelines and best practices specifically in the area of disaster victim identification. In 2009, the Federal Bureau of Investigation (FBI) in the USA received funding to assemble a Scientific Working Group on Disaster Victim Identification. Although this group has no enforcement function, its efforts are intended to generate consensus among practitioners in disaster planning, response, and victim identification through the recommendation of best practices and an emphasis on quality control and assurance. These documents are made available for public review and feedback as a way to encourage maximum contribution and acceptance.

The growing membership of physical anthropologists within the American Academy of Forensic Sciences and the American Board of Forensic Anthropology is also reflective of an expanding interest in the medicolegal aspects of disaster response and victim identification. Traditional employment opportunities for forensic anthropologists at universities and other research institutes have expanded to include agencies focused specifically on mass fatality issues, human rights and humanitarian organizations; federal, state, and city medical examiner's offices; crime laboratories; emergency management departments; public health and safety offices; and the armed forces. In fact, the largest numbers of staff dedicated to the practice of forensic anthropology in the world today is the Central Identification Laboratory, comprised of multiple facilities run by the US Department of Defense and accredited through the American Society of Crime Laboratory Directors/Laboratory Accreditation Board.

Forensic anthropologists with technical expertise in archaeology are treating disaster scenes as large-scale death investigations requiring the use of scientifically validated field methods and techniques. As a result, their research is expanding rapidly into the wider application of spatial data analysis and visualization, mapping systems and technologies, and the quality assurance and control measures that define effective survey and recovery operations.

The accurate identification and efficient return of disaster victims to their loved ones is an integral part of the grieving process that transcends all cultural boundaries. In its current state of development, forensic anthropology and its use of standardized archaeological field procedures, has begun to take a new role within the framework of disaster response, providing medicolegal authorities with more consistent and reliable ways of detecting, mapping, and recovering victims. Amid the chaos of a disaster, it is only through comprehensive scene processing and interpretation that the complexity of the incident can be understood and articulated in a way that strikes an effective balance between the concerns of the bereaved and the responsibilities of the medicolegal authority.

Forensic Anthropology: Definition

Luis Fondebrider
The Argentine Forensic Anthropology Team (Equipo Argentino de Antropología Forense, EAAF), Buenos Aires, Argentina

Brief Definition of the Topic

Since the development of the discipline, forensic anthropology has been defined in different ways depending on the context (Blau and Ubelaker 2009). Initially defined by Stewart (1979: ix), forensic anthropology was seen as "the branch of physical anthropology which, for forensic purposes deals with the identification of more or less skeletonized remains known to be, or suspected of being human." In 1977, an official definition was provided by the American Board of Forensic Anthropology that defines forensic anthropology as "the application of the science of physical or biological anthropology to the legal process. Physical or biological anthropologists who specialize in forensics primarily focus their studies on the human skeleton" (http://www.theabfa.org/).

More recently, the Scientific Working Group for Forensic Anthropology (SWGANTH) proposed a new definition: "forensic Anthropology is the application of anthropological methods and

theory – particularly those relating to the recovery and analysis of human remains – to resolve legal matters" (http://www.swganth.org/index.html).

These definitions illustrate the wide role that forensic anthropology practitioners have been developing over the last 30 years: from an initial specific role analyzing skeletal remains to a wider contribution that today incorporates the archaeological recovery of human remains, the analysis of taphonomic processes and the analysis of perimortem bone trauma.

The expansion of the application of forensic anthropology also highlights the undefined boundaries of the discipline. This broadness sometimes creates confusion for lawyers and police forces in terms of what is possible to expect from a forensic anthropologist.

More recently, forensic anthropology has been applied to the investigation of human rights violations. Such work is redefining the role of forensic anthropologists in the identification process and their role in the collection and analysis of antemortem data.

It is worth mentioning that perceptions about the role of a forensic anthropologist differ from country to country. In some contexts, forensic anthropologists almost exclusively analyze skeletal remains in order to produce a biological profile; in other contexts, practitioners are involved in physical work at the crime scene, involving fleshed remains and bones; in others, they also incorporate the analysis of different kinds of trauma in the skeleton, complementing the work of the forensic pathologist, and in others, their work involves also the analysis of living people, in terms of age estimation of migrants, for example.

In conclusion, the traditional concepts that are usual to mention when talking about forensic anthropology, as "skeletal remains," "physical anthropology," "identification," and "biological variability", are increasingly expanding. A forensic anthropologist may work at the crime scene (survey, recovery, taphonomy, interpretation), at the laboratory (trauma, disease), and in antemortem data collection.

Finally, it is important to remember that a forensic anthropologist is primarily an anthropologist, someone with a wider background than a forensic odontologist or a forensic pathologist. This may be an advantage in the understanding and comprehension of processes in forensic contexts, where cultural and religious elements could play an important role.

Forensic Anthropology: Investigating Human Rights Violations

José Pablo Baraybar
International Committee of the Red Cross (ICRC), Geneva, Switzerland

Introduction

The contribution of forensic anthropology and archaeology to human rights revolves around three

core concepts: historical record keeping or "getting the record straight," enforcing "the right to know" of surviving families, and the creation of new approaches in the "jurisprudence" pertaining to interpretation of evidence about violations against international humanitarian law and international human rights law.

Definition

Forensic anthropology and archaeology have significantly improved human rights work throughout the world, from the starting point of investigations carried out on the after effects of armed conflicts where state officials perpetrated massive human rights abuses. International instruments set forth by the UN to prevent crimes against humanity, such as the *Geneva Conventions*, *the Convention on the Prevention and Punishment of the Crime of Genocide*, and the *Convention for the Protection of All Persons from Enforced Disappearance*, have set the groundwork for forensic anthropology and archaeology to be included in the investigative strategies used for legal purposes, historical reconstruction of events, and humanitarian identification. These scientific fields use a variety of methods for data gathering and analysis. The physical records they gather help to establish human behavioral patterns that provide important clues to clarify the most probable sequence of the events that occurred at a given location at a specific time.

Key Issues

To understand the importance and nature of these contributions, it is important to observe the work involved with each of the three main purposes separately. The three key issues are identified and categorized as historical revisionism ("*getting the record straight*"), jurisprudence, and humanitarian identification ("*the right to know*").

Getting the Record Straight

Human rights advocacy entails, among other things, trying to establish the factual truth for the historical record of events. In this regard, a fundamental contribution is objective statistical analysis based on good data gathering and accurate physical records. Good statistical practices are crucial in order to dismantle false records and assure historical truth.

Jurisprudence

Legal forensic interpretations of data are very challenging in cases where there are large numbers of victims. New and more complete means of interpretation are increasingly requested from forensic anthropology and archaeology. The following are three concrete examples of different patterns observed:

Demography of Genocide (Krstic IT-98-33; Popovic et al. IT-05-88; Tolimir IT-05-88/2)

Analysis of the age and sex distribution of a large number of cases demonstrated that the victims were not random but rather were part of a selected population: "men of fighting age."

Torture (Limaj et al. IT-03-66)

Analysis of the remains of ten individuals alleged to have been kidnapped and imprisoned in a clandestine detention center by the Kosovo Liberation Army (KLA) demonstrated that their injuries matched the description provided by the only surviving victim of what was inflicted by their captors and fell within the time frame of the detention.

Injury Patterns in Combatants Versus Noncombatants (Dordevic IT-05-87/1, Nova Brasilia vs. Brazil)

It was determined that the distribution of injuries in combatants and noncombatants is different. While the latter sustained gunshot injuries with greater frequency in the extremities and then in the chest and with the least frequency in the head, victims of human rights violations do so in the opposite manner: most frequently in the head, then in the chest, and least frequently in the extremities.

The Right to Know

The right to know what happened to a relative is said by the ICRC to be a fundamental pillar of international humanitarian law, and all countries and conflicting parties should respect and follow this law of war. Forensic anthropology is fundamental to reaching the humanitarian

purpose of identifying victims. As a result it is a key tool for victims and associations of victims of forced disappearance, extrajudicial killings, and the like.

Current Debates and Future Directions

Traditionally, forensic sciences have been considered principally as a means to establish the truth with the ultimate goal of administering justice. This concept is expanding, however. The "humanitarian umbrella," for example, is an initiative which seeks to prioritize the right to know of surviving family members through the identification of victims before legal processes. There are also human development initiatives arising from the contact with the communities. Understanding who the victims are and what interactions with other actors are generated during forensic interventions has increasingly gained relevance. The victims are often the poor, the illiterate, and the minorities, individuals whose position in society made them susceptible to various violations of their economic, social, and cultural rights which were not respected, defended, or enforced. This leads to an important question: would the proper respect and guarantee of civil and political rights alone, as traditionally pursued in truth-seeking mechanisms and trials, allow those victims to undertake the long path to recover their condition as citizens, if they were not considered citizens to begin with? Individuals become survivors in a system that tolerates them as objects but not as subjects of rights: the natural transition from victimhood is to survivorship. Perhaps the full enforcement not only of civil and political rights but also of economic, social, and cultural rights is the key to enable a further transition: from victims to citizens.

Forensics, when applied to the "illustration" of human rights violations, has the power to produce social change since it establishes a link with communities that choose to remember. Investigating these types of crimes is a long-term process. Its success depends on systematic strategies for preliminary investigations including antemortem data collection and grave record collection of missing persons. Understanding memory becomes, in this case, a mechanism for empowerment, a means to establish transactions between incontrovertible facts and constituencies with contentious memories of facts. This is the "illustrative" power of forensics.

Forensics need to be used in a proactive way so as not only to illustrate victims' suffering but also to provide a chance for compensation and also to remedy the unfavorable conditions that converted people into victims in the first place. This means highlighting the causes and not just the consequences of marginalization and exclusion. By profiting from the spree of change sparked by forensic intervention in a community, survivors are empowered to start their path to citizenship. This, in turn, forces the State to fulfill its obligation to enforce economic, social, and cultural as well as civil and political rights, often overlooked in processes of transition, and to guarantee all rights of new "citizens" forged in this struggle. Reconciliation or perhaps "less contentious coexistence" is achieved when transactions of memory are carried out in order to contrast that memory with the incontrovertible evidence that forensics provides. A semblance of collective memory is then achieved.

Form in the Archaeology of Art

Marcela Sepúlveda
Universidad de Tarapacá, Arica, Arica y Parinacota, Chile
UMR 8096 ArchAm (CNRS-Paris 1), Paris, France

Introduction

The study of form or morphology is one of the fundamental bases of classification analysis in the archaeology of art. Unlike anthropology that denied the study of art almost entirely until the 1960s (Morphy 1994), archaeology of art was established at the beginning of the twentieth century. It began with the study of form as general configuration of the object, to establish the first typological or stylistic classifications of the "primitive," prehistoric, or exotic arts. Today, recent trends linked to material culture studies allow us to go beyond initial, essentially descriptive and functional, approximations of these visual artifacts to deal with form in its material dimension.

F

Definition

Form, in archaeology of art, is defined as the fundamental physical property of an object, its own three dimension, from its material composition to its constructive composition and contrast with its environment. In the archaeology of art, the study of form corresponds with the analyses of the different properties of the objects or visual arts relating to their general configuration or outline (contour), their size, their shape, their texture, their color, and relationship with space. In methodological terms, the study of the form of visual artifacts implies their analysis as a visual system through the selection and definition of specific morphological attributes, emanating mostly from the history of art and semiotics. At an interpretive level, the study of form has been traditionally linked to the search for the significance and accuracy of its function, touching on established focuses from the analyses of perception and aesthetics.

Key Issues

Form currently possesses various meaning and applications in archaeology of art. This is due, among other reasons, to the fact that its study formed one of the first pillars of archaeology as a discipline and to the diversity of focuses that have been covered in the study since then. Since the beginning of the twentieth century, form, limited to the study of outline (as with iconography), contributed to the definition of countless

seriations, typologies (Adams and Adams 1991), and styles, by way of arranging a set of visual evidence of which the chronological attribution established itself relatively. Form as outline was initially analyzed as an external aspect or the general configuration of an object or image, in order to later tackle the constituent elements of the form. The first studies of form meant to distinguish images or visual objects in terms of natural or abstract or geometric forms; on the basis of its size (small, medium, large); in terms of its color, referring to the surface or exterior of the object or image; in terms of its texture (rough and smooth, among others); and on the basis of its distinction from its environment or base. At that time, the visual object was limited to the study of the content or configuration established in the outline or silhouette, taking into account different attributes that constitute its general morphology. In the analysis of animals in European art, this meant studying the number and placement of paws, of ears, and of the head to define a series of perspective forms, understanding that these visual configurations had a relative chronological value (Breuil 1952). Under the influence of the French structuralist school, the study of form as composition, defined as the spatial relationship and compositional logic established between the parietal images, would later be addressed for the definition of styles (Leroi-Gourhan 1968) and accuracy of meanings (Raphael 1986).

Current Debates

This structuralist vision is taken up again and amplified, from the 1980s through post-processual or New Archaeology whereby form is defined as a complex visual system requiring codes or grammatical specifics and Cultural Semiotics (Layton 2006), in relation with determined local contexts (Preucel and Hodder 1996). The study of form as composition is also extended, for example, to the study of the structure of iconography by way of language (Washburn and Crowe 1988). More recently and in this same logical framework, form has been understood also from the point of view of the spatial relationships between objects at a macroanalytical level, the conception of which constitutes one of the foundations of landscape archaeology. Regardless of these different meanings, the discussion of the relationship between form and function has undoubtedly occupied a special place in archaeology of art. Form as essence of style and form as a result of the selection between functioning alternatives have oriented the debate towards the functionality of the form and its meaning in the 1970s and 1980s. Consequently, form has been defined as an ethnic or territorial marker, a differentiator of role, status, or genre, among other things (Dunnell 1978; Sackett 1982, 1985; Wiessner 1983, 1985; Conkey and Hastorf 1993). In the last few decades, from the material culture (Tilley 2006) and technology (Sigaut 2004) perspectives, the analysis of form of visual artifacts incorporates, beyond its physical appearance, the study of its materiality. That is to say, it considers the materials, knowledge, abilities, techniques, and specific movements used in the different stages of its production (Sepúlveda 2009; Fiore 2011). As a visual system, the materiality of a form implies cultural decisions, particularly in relation to temporal space contexts. Because of the broadening of previous, essentially functionalist, views, form today could also be interpreted in terms of culture, in terms of material, economic, and social implications, and more.

Formal Education up to Age 18, Archaeology in

Donald Henson
York, UK
Institute of Archaeology, University College London, London, UK

Introduction

When we look at the place of archaeology in formal education in the United Kingdom, we see a paradox. Archaeology is extremely popular with the general public and with the media. Millions of people are members of organizations like the National Trust, up to 3 million viewers will regularly watch TV programs on archaeology, many thousands attend events such as the Festival of British Archaeology, and over 200,000 are members of local societies and clubs concerned with the historic environment, and yet archaeology has no explicit place in the school curriculum. The reason may be simple, that archaeology had not yet established itself as an academic subject in universities at the time when the school curriculum was being determined in the later nineteenth century. Subjects like history and geography were well established and could claim a presence in the curriculum. The nineteenth century curriculum has proven very hard to change and is still the basis for education up to the age of 18.

However, this is unlikely to be the only reason for archaeology's unpopularity with educators. Archaeology is widely seen as a technical and physical discipline concerned with excavation and recording of remains and, therefore, of less academic standing than a purely intellectual subject than history. This was for a long time an attitude among historians that archaeology was the handmaiden of history, providing physical backup for the written record of the past. This attitude is no longer part of academic discourse in archaeology or history, and yet it does still seem to be held by many outside the hallowed halls of academia. The great advances in archaeology

from the 1960s onwards which have shifted archaeology away from culture history towards more sociological, geographical, or psychological interpretations of the past and toward a more self-reflexive questioning of archaeology's role and purpose have yet to find their way into popular understandings of the subject.

Key Issues

The traditional method of educational delivery is of the didactic provision of information. Bodies of knowledge as structured facts about the world or as agreed narratives are the life blood of teaching. Over the last 20 years, there has been a move towards balancing imparting knowledge with the acquisition of skills. There has also been a longer-term move towards more child-centered approaches to education. In practice, the assessment of learning in formal examinations at 16, 17, and 18 still privileges knowledge. Universities continually complain that their new entrants are unable to work independently and expect to be spoon-fed ideas and facts. In such a situation, archaeology is at a disadvantage. Archaeological facts belong firmly within the discarded tradition of culture history. Newer forms of archaeology are based around contested interpretations, and single narratives are hard to find in modern archaeological publication. Archaeology is too contested and uncertain of its knowledge base to be easily delivered as a subject in schools.

This weakness of archaeology is, however, also its strength. Archaeology offers more than knowledge. It is a set of processes involved in learning about the past and in understanding the role that the past could play in people's lives today. It offers critical thinking of an advanced kind. It can give students of all ages intellectual challenge and fascination, as well as deep emotional engagement. The variety of work involved in archaeology can reach every kind of learner. It is especially well geared towards supportive constructivist education. To understand why, we must understand what archaeology is. It is not the simple accumulation of artifacts and sites from the past. It is the study of human life and behavior as reflected in those artifacts and sites. Archaeologists study people, not things. All aspects of human existence are reflected in archaeology. All kinds of analytical, recording, and descriptive processes are involved in archaeology. Archaeology can support every subject in the school curriculum.

Most archaeologists do not understand education. There is a long tradition of thinking about education. Education theory is complex and contested. A range of thinkers and educators have provided different models of how children learn. One early influential thinker was the developmental psychologist Jean Piaget, who came up with a chronological scheme for how a child's mind assimilates information, a kind of cognitive learning theory. The earliest stage is the sensorimotor, from birth to approximately 2 years old in which the child explores the world directly through action. The preoperational stage lasts from 2 to around 7 years old, where objects are associated with words and learn to classify things by their characteristics. Concrete operational thinking follows from around 7 to 11 years old in which the ordering of information becomes more sophisticated. Children at this age can manipulate more than one variable at a time and think in terms of hypotheses, asking "what if" and thinking about the consequences of this. From the age of about 11 onwards, the mind enters the formal operational stage, involving abstract reasoning, thinking about hypothetical futures and ideologies. Where followers of Piaget may have erred is in assuming his stages of development replace each other rather than build upon and extend each other. There is a common and fallacious assumption that as children develop, the intellect takes over from more physical ways of engaging with the world and that abstract thought is a higher form of thinking than concrete thought. If archaeology is seen as a technical exercise in finding, classifying, and recording artifacts, then it is hardly worthy to be taught alongside subjects like history. Indeed, we shall see that where archaeology is used in schools, it tends to be used with younger ages below the age of 11. By looking at the work of more recent educational theorists, we can see how wrong this is.

Another cognitive psychologist whose work has been important for education was Lev Vygotsky, who stressed the importance of the social context of learning. Vygotsky understood how children need to make sense of the world and internalize their external experiences. Most children do not learn in isolation. Learning is a social process where children exchange ideas and information with adult and with each other. The role of teacher is one of enabling and guiding rather than telling. The setting of puzzles or problems to be solved is a legacy of this way of seeing education, as is the creation of group activities where dialogue is part of the learning process. The necessity for teamwork in archaeology and the intellectually challenging nature of archaeological inquiry are clearly well suited to social learning.

Vygotsky's ideas are the basis of constructivism, in which children construct their own understanding of the world from the stimuli they receive from others. The theorist who did most to develop a constructivist theory of learning was Jerome Bruner, who stressed the importance of active learning by structuring knowledge into forms suitable for the child, building on existing skills, stimulating self-discovery, and learning by doing rather than listening. Good teaching should understand the child's motivations and willingness, or otherwise to learn, and should be designed to stretch the child to go beyond what it taught and to extrapolate or fill in gaps in knowledge and understanding. Again, archaeology has advantages for this kind of learning in that it is tactile, necessitates going beyond the immediate evidence, and has an innate fascination that makes children want to learn.

It is now appreciated that not all children learn in the same way. However, there is little agreement on the different ways in which children learn. One simple and easily applied scheme is the taxonomy of learning devised by Benjamin Bloom. Bloom identified three domains of learning: cognitive, affective, and psychomotor. Cognitive learning involves the assimilation of knowledge and development of thinking skills. Such skills would include pattern recognition, devising abstract concepts, evaluating data, solving problems, and justifying arguments. All of these are clearly involved in archaeology. Affective learning involves making use of our emotional responses to things. This involves understanding our attitudes, ethical standards, making judgments, and being artistically creative. Again, all of these can be found in archaeology. Psychomotor learning involves the development of physical skills. Archaeology of course uses a great many such skills. It is perhaps significant that there is an unspoken hierarchy of domains in that cognitive learning is rated above affective learning, which in turn is rated about psychomotor learning. The scientist ranks higher than the painter who in turns ranks higher than the plumber. This is wrong and highly unfortunate. All three domains are an equal part of learning, and archaeology is one of the rare subjects able to include them in the same activity.

Another popular way of looking at different ways of learning is the experiential learning theory of David Kolb. This envisages learning as the reaction to a four-stage cycle of understanding. Concrete experiences are used as a basis for making observations and reflections, which in turn lead to developing abstract concepts. These are then used to derive implications for active testing, which in turn produces concrete experiences, and so the whole cycle begins again. Some people are better than others at learning in different parts of the cycle, depending on their preferred learning style. There are four such styles: feeling and watching, watching and thinking, doing and thinking, doing and feeling. Archaeology involves both thinking and doing but also thinking and watching, being able to make sense of information gathered by others. There is a clear sense in which the divergence between processual and post-processual archaeology can be understood as the irreconcilable opposition of different learning styles, where those who feel were asking for equal space alongside those who think.

Perhaps the most widely known learning theory of recent years in the heritage sector is Howard Gardner's multiple intelligences theory. Gardner's idea is that the human mind is wired up to see the world in different ways and that we all have a combination of at least eight different kinds of understanding or intelligences. Linguistic

intelligence is the ability to understand and use the spoken and written word. Mathematical-logical intelligence involves analyzing problems and understanding logical relationships. Musical intelligence involves recognizing and using sounds rather than words, with the ability to distinguish pitch, tone, and rhythm. Kinesthetic-bodily intelligence involves being able to coordinate bodily movements and solve problems by doing rather than thinking. Spatial intelligence involves awareness of space and spatial patterns. Naturalist intelligence involves being able to observe, classify, and categorize the world around us, spotting its patterns and potential. Interpersonal intelligences involve empathizing with others and working well within teams. Intrapersonal intelligence is a capacity to know yourself and understand our own interactions with others. Most people have all eight but usually have two or three dominant intelligences. Apart from musical intelligence, these are all a natural part of doing archaeology. The lone researcher who likes to solve the problem of untangling the palimpsest of features in the landscape would score highly in intrapersonal, naturalist, and logical intelligences. The excavator who loves being on site and unraveling contexts would score highly in spatial, kinesthetic, and interpersonal intelligences. Gardner's ideas are ideal for use in heritage education where artifacts and sites can be understood through different learning approaches. Children can be asked to write a guidebook for a historic site, sort artifacts into types, investigate why sites are where they are on a map, work in groups to say whether a site was used for domestic or religious purposes, or be asked to write a personal description of poem based on their favorite artifact. All these activities will involve different mixes of intelligences. There are very few children who cannot engage with archaeological evidence as a way of learning.

Archaeology then is ideal for learning, no matter what the educational theory that underlies the curriculum or teaching in the classroom. It is concerned with the physical manipulation of evidence. This evidence comes from real people with whom we can make an imagined emotional connection. Making sense of the evidence involved solving puzzles and problems and using words to express and debate our ideas. We work in teams, yet can also have intensely personal responses to the past. We use science and technology in our work. We make use of artistic representation and delve into all aspects of past life from exploiting the environment to religious belief. Archaeology can not only reach every learner, it can also support every subject on the school curriculum.

The United Kingdom Perspective

School curricula in the United Kingdom are developed separately in England, Wales, Scotland, and Northern Ireland. A national curriculum was first introduced in England from 1988. All the curricula have been revised a various times and continue to be under revision. The curriculum orders have often made reference to the evidence of the past in various of the subjects. In spite of this, and the utility of archaeology for a range of subjects, archaeology has mostly been used in support of history or, occasionally, geography. It is also more used for teaching children aged below 11 or 12.

It has proved hard to get any explicit reference to archaeology in the various curriculum orders and guidelines. There has always been reference in the history orders in England to artifacts, buildings, and sites as sources of evidence and more recently of museums as places that should be visited. The work of archaeologists was only included as an example in the latest form of the orders, under the skill of interpretation. The key historical skills to be taught have included chronology, the facts about events and life at different times, how the past is interpreted, the types and uses of historical evidence, and communicating an organized historical narrative. Archaeology can play a role in all of these but was most used as a way of interrogating physical evidence for life in the past, often using the key question "how do we know what life like at that time?" Archaeology was clearly seen a methodology for studying the past. Conspicuously missing from the curriculum was any reference to prehistory. The periods of time to be taught in primary schools (up to the age of 11) were highly selective. These were mostly Roman Britain, the Anglo-Saxons, the Vikings, Tudor times, the Victorians, Britain in the 1930s

and 1940s, ancient Greece, and usually ancient Egypt. Archaeology of course came into several of these periods. The history taught in secondary schools after the age of 11 dealt with all of history after the Norman Conquest of 1066 along with some European history (often the Roman Empire) and one world history topic. Most of the secondary history could safely include traditional political and socioeconomic documentary history. The lack of prehistory involves pupils knowing nothing of the development of humans as a species or of the settlement of the British Isles and its continuous occupation from around 15,000 years ago until the Roman involvement in Britain 2,000 years ago. The shaping of the British landscape and the development of society and its rituals as reflected in iconic sites like Stonehenge were ignored.

A comparison between the history taught in different pasts of the United Kingdom is instructive. There are clear differences between the four nations, which reflect the different political and cultural relationships that each nation has with the past. In Wales, there was explicit reference to teaching about the earliest inhabitants and the Iron Age Celts. Some 1,500 years after the Anglo-Saxon migration and conquest of southeast Britain, there is still a sense of continuity between modern Wales and the prehistoric past that is missing in England. There was no mandatory study of ancient Greece in Wales and instead a much greater concern with local history. Likewise, in Northern Ireland there was a concern with prehistory from the Mesolithic onwards as part of Irish identity. The Irish have deep historical roots, partly rooted in literary myth, but nonetheless deeply felt, and prehistory provides a noncontentious way of providing an identity separate from that of Britain. The teaching of the medieval past immediately polarizes between the history of the native kings and the incoming English lordship. Likewise, the Vikings were active throughout the British Isles and so not uniquely an Irish experience. In Scotland, prehistory was never emphasized as it was the medieval period which provided Scotland with its roots and identity. What Scotland did have that the other nations did not was an explicit recognition in the rationale for teaching history as a subject of the importance of the historical heritage of Scotland for tourism and the economy. History had a purpose beyond mere curiosity about the past. This linked history with heritage and could allow teachers to touch on the historic environment and issues involved in its management and conservation.

Whatever the guidelines and orders of the curriculum, teaching of history is in the hands of teachers. History teaching is far from homogeneous. There are different visions of the kind of history that should be taught and deep divisions within history teaching. These divisions can be simplified into a polarity between teaching knowledge and teaching skills. The balance between knowledge and skills has often been one of the debated topics during curriculum reform or revision. Traditional history teaching until the 1970s focused on the acquisition of historical knowledge and dates of events and of kings and queens. History was equated in the popular mind with knowing what happened when. This is still the attitude of many. Repeated newspaper scare stories about the inadequacy of history teaching usually involve showing how little people know about dates, events, and famous people in the past. This kind of history is often closely tied to national history and notions of national identity. Good history is deemed to be the history of the nation. Archaeology suffers badly under such a regime of history teaching since it rarely provides a chronological narrative or association of site or events with names individuals.

A reaction against this kind of history began in the 1960s among teacher dissatisfied with didactic teaching. An article by Mary Price in 1968 called for the use of primary sources in the teaching of history in schools. This became a reality with the formation of the Schools Council History Project in 1972. This body still exists as an association of like-minded teachers as the Schools History Project (SHP). The SHP approach is based on the teaching of historical skills, using primary evidence. It moves history teaching away from a narrow focus on dates, events, and personalities towards understanding past ways of life, motivations, and contested interpretations. Many members of the SHP are sympathetic towards the use of

archaeology in teaching history precisely because it allows (even demands) the exploration of issues relating to historical methodology. The SHP produces resources and teaching ideas, many of which include archaeology. A key member of the SHP, Ian Dawson, has made resources for teachers at all levels of education available from his Thinking History website (http://www.thinkinghistory.co.uk). These often include archaeology.

The SHP principles have been followed in the creation of history qualifications at GCSE and A level. These balance learning about the development of a theme over a long time scale and the history of one particular time in depth. The development studies include warfare, medicine, and crime and punishment. Some of the qualifications also focus on using historical evidence. Archaeology can be a part of these qualifications, in a supporting role to history. Archaeology has more of a presence in the GCSE History Pilot that was developed to move history away from its traditional emphasis at GCSE on the nineteenth and twentieth centuries. The Pilot ensures that medieval history is covered and that there are options on archaeology and heritage management. Although useful, the Pilot is not a replacement for the GCSE Archaeology that was abolished in 2004. This had been an excellent introduction to the subject. Its abolition was unjustified and contested in vain by the Council for British Archaeology and others. There is still an A-level Archaeology (run by the AQA awarding body), which is a rigorous and challenging qualification which equips students well for further study. There is also some archaeology within GCSE and A-level Classical Civilization and A levels in Travel and Tourism. In Scotland, there is some archaeology in Standard Grade Classical Studies and as options in Highers.

One reason why the GCSE Archaeology was abolished was the low numbers of students taking the exam. This was partly a product of the difficulty that archaeology graduates have in becoming school teachers. Without teachers who have a knowledge of archaeology, there are few incentives or confidence to use it. Some teacher training institutions have taken a very strict attitude that only graduates in subjects that appear in the national curriculum can be accepted for training as teachers, especially for teaching at secondary level. This is unfortunate and not the intention of the teacher training regulations. It is far easier to be accepted for teacher training with a joint archaeology and history degree than with a single honors archaeology degree. There are some enlightened training colleges and universities who will take archaeologists, but there are still too few teachers with a knowledge of the subject and confidence to use it within their teaching.

Future Directions

Archaeology is a wonderful subject for use in teaching all ages of children. It can inspire and enthuse otherwise demotivated pupils. It can stretch and challenge to high attainers. The nature of archaeological evidence and methods is ideal for meeting the needs of different learning styles and intelligences. Yet, archaeology as practiced by archaeologists has weaknesses. The end product of research is seldom synthesized as narratives of the past, and many aspects of archaeological practice are only debated or explained in esoteric or hard-to-obtain academic forums. The full richness of archaeology is not as accessible to teachers as it should be.

The way to make archaeology more accessible and available is to make sure that archaeology finds its place within wider educational contexts. Recent initiatives in England have sought to improve the use of the built environment and out-of-classroom resources generally by teachers. Archaeology obviously has a place within these. The Engaging Places initiative has the aim of encouraging teachers to make more use of the built environment. This could easily be dominated by contemporary architecture, but from the beginning, the Council for British Archaeology was able to make sure that the historic environment was also included. All environments have a historic element, and archaeologists can enable people to see this and make use of it. The Council for Learning Outside the Classroom has a wider aim to encourage learning in real-world situations outside of the classroom. Heritage is one of the eight sectors within the council, and archaeology is clearly a

key arena for real-world learning. Again the Council for British Archaeology played a key role in the early formation of the Council.

We also need to make sure that heritage educators improve the quality of their work with schools and the public. No matter how good the offering is, there is always room for self-reflection, evaluation, and improving the learning outcomes for pupils and students. The Council for Learning Outside the Classroom has instituted a quality badge for providers of educational opportunities. Another organization, the Heritage Education Trust, issues the Sandford Heritage Education Awards for the provision of quality education by heritage sites. More and more archaeologists are working with schools and have the skills and knowledge to make use of opportunities such as these. Many field units and local authority archaeology services now provide resources for teachers to make use of archaeology within the curriculum.

Fort Odanak Archaeological Project

Geneviève Treyvaud
Laboratoires d'archéologie, Laval University, Québec, QC, Canada

Brief Definition of the Topic

Since 1979, the High Council of the Waban-Aki Nation, commissioned by two band councils of Odanak and Wôlinak, has had a mission to ensure the future of the Abenaki Nation by offering a series of studies related to the documentation of their past and the promotion of their culture. It thus seems only natural to integrate archaeology in this process. It was in 2010, with the collaboration and

financial support of the Department of Canadian Heritage, the Abenaki Museum, and the Odanak Band Council, that the Fort Odanak archaeological project began under the responsibility of two archaeologists: Geneviève Treyvaud and Michel Plourde. They set up a research project aimed at discovering the missions and the Abenaki fort and by extension, a better understanding of their way of life in the "Transition" and "Colonial" periods. This project lasted 3 years and ended with the publication of a report and the establishment of a semipermanent exhibition.

The Abenaki territories of Wôlinak and Odanak are the only two Abenaki communities recognized in Quebec. The village is situated in the MRC (regional county municipality) of Nicolet-Yamaska on the eastern shore of the St. François River, 32 km east of Sorel and near Lake St. Pierre. The community counts about 1800 residents, 400 of which reside in Odanak. The land area is 6.07 km^2. It is composed of upper and lower riparian terraces, some islands upstream and downstream of the village, as well as two woodlands located in the municipalities of Saint-François-du-Lac and Pierreville.

The excavations in 2010 found two archaeological sites: CaFe-4 dating to the Woodland period and CaFe-5 dating to the Archaic. In the fall of 2012, an inventory was undertaken on the historic quadrilateral of Odanak. An important archaeological site, CaFe-7, was excavated. This site presents many occupations dating from the Woodland period until today. The artifacts and the relics discovered, as well as stratigraphic levels, have enabled the identification of an occupation contemporary to the fortified village at the beginning of the eighteenth century.

Fortea, Javier

Josep Maria Fullola
Departament de Prehistòria, Història Antiga i Arqueologia/SERP, Universitat de Barcelona, Barcelona, Spain

Basic Biographical Information

Javier Fortea (born in Arnedo (La Rioja, Spain) in 1946; died in Oviedo (Asturias, Spain) in 2009) studied Philosophy and Arts, with an expertise in History, at the University of Salamanca between 1963 and 1968. In this same university, Professor Francisco Jordá became his academic guide into Palaeolithic research, with a special focus on the Upper Paleolithic and Epipaleolithic periods. He received his Ph.D. in 1972 from the University of Salamanca with an in depth dissertation on the Epipaleolithic sequence of the Mediterranean area of Iberia (Fortea 1973), which is still a reference work for anyone studying this period.

Up until 1979, while being assistant lecturer at the University of Salamanca, his research was mainly focused on a specific geographical area, the eastern part of Iberia, and more specifically on the central area: Valencia. The excavations of Mallaetes and Cocina caves, together with the studies of other lithic industries and art evidences from other key sites, provided him a wide picture to suggest a robust synthesis of the Upper Palaeolithic in eastern Iberia, from Catalonia to Andalusia (Fortea et al. 1983). His approach to rock art research also began with a very important *status quaestionis* of Palaeolithic art in the Mediterranean area (Fortea 1978).

In 1979, his academic career took a turn, as he became Professor of Prehistory at the University of Oviedo, in Asturias, one of the richest European regions in Upper Paleolithic sites and rock art caves. The excavations conducted at two main sites, La Viña and Llonín, gave him the opportunity of introducing innovations in the archaeological methodology and finding important series of Upper Palaeolithic bone and lithic industries.

But his rock art discoveries and research mark the highlight of his scientific career. New sites as Covaciella and El Bosque were studied, dated, and published, becoming part of the list of ornamented caves of Western Europe. He had a special interest in the precise dating of the animals represented in Upper Palaeolithic caves, and he devoted most of his time and efforts to work closely with the laboratories to assure that the resulting dates were correct (Fortea 2002).

His international papers on rock art were very appreciated by foreign colleagues; each paper being the product of in depth research. It means that Professor Fortea did not publish hundreds of papers and thousands of pages, but each of them was so solid that they could easily resist the passing of time.

Some English-speaking colleagues, such as Ian Davidson and Lawrence Straus, were well aware of the scientific achievements of Professor Fortea, as they worked for many years in Spain and met him often to debate about their common research interests. He became a member of many international institutions, although he always preferred working in the field and in the laboratory, more than assisting to hard and nonproductive meetings. Perhaps, his most important international positions were being member of the Upper Palaeolithic Commission of the UISPP and of ICOMOS.

Major Accomplishments

Professor Fortea's most important accomplishments took place in France. He collaborated with Jean Clottes in the research teams that studied the new rock art discoveries at Cosquer, Coussac, and, the most important, Chauvet. And, in the last decade, he studied and published many papers with Georges Sauvet, Carole Fritz, and Gilles Tosello (Sauvet et al. 2008, among others) concerning key aspects of rock art, such as styles and chronology.

One of Professor Fortea's creations, which will last forever, was the archaeological park of prehistoric art of Teverga. In this little town of Asturias, in the mountains, he offered the public a walk along the birth of prehistoric art, with visits to real size reproductions of three significant sets of European Palaeolithic with paintings and engravings. In Teverga, Professor Fortea applied all his knowledge in the service of society to give to the public an understanding of prehistoric art.

The last years before his death in 2009, Professor Fortea was involved in a very high-level scientific research concerning Neanderthals and their DNA sequence. Together with his collaborator Marco de la Rasilla, also from the University of Oviedo, he began working at El Sidrón cave, where they discovered the best-preserved Neanderthal remains to obtain DNA. The collaboration with the most important international specialists in the field provides Professor Fortea his last projection with several impact papers (Torres et al. 2010; Green et al. 2010).

Fortifications, Archaeology of

Tony Pollard
Centre for Battlefield Archaeology, University of Glasgow, Glasgow, UK

Introduction and Definition

Defensive structures come in a wide variety of forms and cover an exceptionally long time frame; indeed there are relatively few societies existing either today or in the past that have not utilized some form of fortification, even if it was just a thorn brush fence around a group of huts. What is not clear is when they first appeared, though Mesolithic (c. 10,000–4000 BCE) possibilities have been cited (Sippila and Lahelma 2006). In their most obvious guises, they range from European Iron Age hillforts to medieval castles, seventeenth-century Anglo-Scottish bastle houses, eighteenth-century fortresses, colonial stockades, and Maori Pãs to First and Second World War concrete defenses, but this list is just the tip of the iceberg. Although this wide portfolio of structures is an obvious response to interhuman conflict, or the threat of it, the nature of this conflict has almost as many variants as there are types of fortifications. This is not however the place to be considering the anthropology of conflict, beyond recognizing that this variation exists.

Limiting this entry to fortifications from the historic period makes the subject matter only slightly more manageable. However, to narrow the field even further, our period will commence with the end of the European medieval period, which conveniently removes most castles from the mix. The beginning of our period was heralded by not just the introduction of gunpowder weapons, which can be traced far back into medieval times, but the point at which they came to dominate warfare, at least in Europe. This watershed occurs at some point in the late fifteenth and the early sixteenth century and is marked by the appearance of new styles of fortification which, following their introduction in the Italian wars, spread throughout Europe in the form of the so-called trace italienne, a largely earthwork fortification designed to withstand the onslaught of heavy artillery. These structures were also known as star forts due to projecting triangular bastions which provided mutual support from the artillery pieces placed in them.

Historical Background

Developments in Europe c. CE 1300–1800

The arrival of cannon in the fourteenth century marked the beginning of the end of the stone-walled castle. Stone balls and then iron fired by cannon of various sizes were very effective at bringing down stone walls, having the ability to punch through even thick masonry. In response to this redundancy, battered earth walls were

introduced. These did not achieve the same height as the earlier stone walls, and the thick masses of earth effectively soaked up the impact of cannon shot while angled faces helped to deflect the blow. This is not to say that stone fortifications were abandoned entirely, and many earthwork forts were fronted with stone. Modifications to pre-existing castles and forts were also common and can be seen in the form of bastions replacing towers, the addition of gun loops, and the throwing up of earthworks around older, stone defenses. The effectiveness of these defenses can be judged by their rapid spread across Europe, which by the early sixteenth century had brought them to the western fringes of Scotland and Ireland. The recent upsurge in conflict archaeology has seen a flowering of interest in these and other fortifications. For example, the archaeological investigation of the battlefield of Flodden, fought in 1513 by the armies of James IV of Scotland and Henry VIII of England, in a hilly landscape not far south of the Scottish border, has brought to light Scottish defenses on Flodden Hill which appear to have been influenced by the Italian school, with triangular buttresses providing a platform for cannon with interlocking fields of fire (an important advantage which these purpose-built artillery forts had over the earlier castles was the absence of blind spots, into which defensive artillery or other firearms were unable to fire). Italian inspired modifications to Edinburgh Castle dating to roughly the same period have also come to light thanks to archaeological intervention within the castle's precincts. In the wake of English victory at Flodden, the town of Edinburgh gained a city wall and the castle also underwent some modification. It was not however until the mid-1500s that substantial new defenses, including a formidable earthen artillery fortification known as the spur, were thrown up. Subsumed beneath the parade ground or esplanade in 1753, the remains of this structure, actually a triangular ravelin, a defensive fieldwork placed in advance of the castle entrance, were exposed during an archaeological intervention related to the construction of stands for the Edinburgh Tattoo in 2010.

As fortifications for defense developed, so did those for offense. Siege warfare reached a peak of sophistication in the medieval period with the evolution of siege engines such as the mangonel, giving the attacker the ability of launching heavy missiles, usually stone, against the walls (Viollet-Le-Duc and Bucknell 2009). Underground, the digging of tunnels allowed attackers to undermine castle walls and towers. However, all of this changed with the widespread adoption of artillery. Artillery allowed attackers to stand off from the target at greater distances, but this did not negate the need to get close enough to deliver attacking infantry into breaches created by the cannon. The need to accommodate artillery and to deliver infantry assault led to the construction of siegeworks, which included artillery bastions, trenches, saps, and mines, which ideally would entirely surround the castle, fortress, or walled town under siege in what was called circumvallation. Siege tactics included the digging of parallels, which as the name suggests were trenches sighted parallel to the defensive walls. These trenches provided cover for the digging of saps, which ran perpendicular to the defenses, heading toward them. Once a suitable distance had been covered, another parallel system was dug to provide a new platform for operations closer to the defenses. During this process the walls were continually bombarded by heavy artillery located further back until a breach was created, by which time troops were theoretically positioned close enough to the walls to allow an attack on the breach from cover rather than a costly charge over open ground.

That fortification and siege warfare were regarded as key aspects of the arts of war is emphasized by the flowering of manuals and scale drawings published from the mid-sixteenth century onward. An impressive example of the latter is the Petworth map (so called because it resides in Petworth House, Sussex) which shows the citadel of Leith, to the north of Edinburgh, which in 1560 was a French enclave, and the surrounding siegeworks thrown up by a combined force of Scots and English. This map was to provide the key to an attempt to locate surviving remnants of the siegeworks within the modern urban environment of Leith, which is now essentially a suburb of Edinburgh (Pollard and Banks 2008a, 2008b). Although the wider landscape was portrayed in three dimensions, the town walls and

siegeworks were based on measured surveys. When these were scaled up and overlaid on a modern street map, it was apparent that elements of the siegeworks corresponded to areas which are free of development, surviving as open parkland (Fig. 1). The resulting project uncovered buried banks and ditches associated with an artillery fort in Pilrig Park, with a metal-working forge in the bottom of the ditch to the rear of the feature – presumably where it was far enough away from powder (Pollard 2008).

The Dutch War of Independence fought against Spain, between 1568 and 1648, was to see a flowering in fortification technologies, though the influence of the Trace Italienne was still dominant. Warfare at this time was characterized by siege warfare rather than open-field battles, and this tendency was only to begin to break down during the Thirty Years War (1618–1648), of which the Dutch war became a part. Gustav Adolf, King of Sweden, followed in the footsteps of Prince Maurice of Nassau and overhauled the way armies operated – largely based around the complex relationship between pike and shot. Many European cities retain at least some vestige of their late-sixteenth-century and early-seventeenth-century defenses, though they have yet to attract the archaeological attention they deserve. When archaeological intervention has taken place, it is usually prompted by urban development, as most of these impressive structures are now embedded within the framework of modern towns and cities. This was the case with the discovery in 2011 of two skeletons of soldiers killed during the siege of Stralsund, a heavily fortified German Hanseatic town on the shore of the Baltic which over several weeks in 1628 was besieged by Imperial troops under Wallenstein (Anonymous 2012). The two men, who were found face down in a ditch and seemed to have been buried where they fell, along with their muskets, swords, and various pole-arms, are thought to have been Imperial Landsknecht mercenaries killed by besieged Protestant troops during a sally outside of the defenses. One thing that this discovery does demonstrate is the rich contexts of burial which fortifications and siegeworks can provide – for at this time formal mass graves on battlefields seem to have consisted of bodies stripped bare of clothing and equipment, as demonstrated by the graves at Leipzig (1632) and Wittstock (1636) – the first of which was discovered thanks to a program of research, the second accidently in a sand quarry (Eickhoff et al. 2008).

Just as the various infantry tactics introduced by Maurice of Nassau, King Gustav Adolf of Sweden and others had an influence on the battlefields of the British Civil Wars in the mid-seventeenth century, so the military engineers of the Netherlands, France, and Italy also played a hand in defining the nature of fortifications during this conflict. Again, sieges rather than battles dominated, with major towns such as Bristol, Oxford, and York having old defenses, usually medieval walls, strengthened and new fieldworks constructed. Siegeworks were equally impressive, though the practice of slighting these and other features after the wars ended has left few surviving examples of upstanding earthworks. Perhaps the most dramatic of these in the British Isles is the Queen's sconce, outside the town of Newark. "Sconce" comes from the Dutch *schans* meaning "small protective earthwork or shelter" and is itself an indication of the importance of continental influence, with early treatises such as *The Practice of Fortification* by Paul Ive (1589) translating techniques into English. At Newark, there were originally two of these artillery positions, a square rather than triangular defense mounded from earth but making good use of a natural rise, outside the main defenses of the town, where they were positioned to provide protective fire from an advanced position. Connecting sconces to one another with ditches and banks was a popular way of providing defense for towns which had expanded drastically since the medieval period, when stone curtain walls were not unusual, and London, Bristol, and Plymouth were just some examples of this type of urban defense (Harrington 2005: 29).

One legacy of the British Civil Wars which has only recently attracted the attention of conflict

Fortifications, Archaeology of, Fig. 1 Details of siegeworks around citadel of Leith taken from Petworth map and overlain over modern map – showing relationship to open spaces

archaeologists is the impact craters created by musket balls and other types of ordnance when they struck stone-walled buildings. The gatehouses of Stirling Castle and Linlithgow Palace are just two examples from Scotland, and similar damage has also recently been identified around the ground floor windows of the tower at Cambuskenneth Abbey. Musket balls indicative of seventeenth-century conflict have also been recovered by metal detectorists in nearby fields, and the two forms of evidence in combination may indicate a previously unrecorded combat on the outskirts of Stirling, perhaps an unrecorded incident from the Battle of Stirling which was fought in September 1648.

The continued process of fortification design in the early modern period reached its climax with Sébastien Le Prestre de Vauban (1633–1707), a French military engineer renowned to this day for his flair for fortress design, though he actually made his reputation in taking forts by siege rather than designing them. Many of the elements of Vauban forts, such as angled bastions, glacis slopes to deflect cannon shot, covered ways, and caponniers, which allowed defenders to shoot along the defensive ditches from cover, can be seen in the earlier trace italienne, but Vauban refined them and combined the key elements to work in conjunction with the terrain. Although Vauban is usually associated with European forts, particularly those in France such as Bayonne, Cambrai, La Rochelle, and Verdun, his influence was to be much wider, with the colonies of various European powers, and most particularly the French and the British, constructing Vauban-style forts in the Americas, Africa, and India.

By the time of the Napoleonic wars, armies were much bigger than they had been for much of the eighteenth century and open-field engagements, of which the Battle of Waterloo in 1815 is the most famous, became more common. Sieges did however still occur, and the storming of French-held citadels such as Ciudad Rodrigo and Badajoz, both in 1812, demonstrated the delivery of infantry to the enemy walls via the trenches, saps, and parallels first developed by military engineers in the sixteenth and seventeenth centuries, while heavy artillery created breaches. The continued use of stone walls, despite angled bastions and other refinements, demonstrated their fallibility in the face of siege artillery, though at Ciudad Rodrigo the breaching was assisted by poor-quality mortar. Storming fortifications was however a costly exercise, and for obvious reasons, the lead units into a breach were known as the forlorn hope. After the death of 3000 British and Portuguese troops in the final assault on Badajoz, Wellington's army wreaked a terrible revenge on the occupants, military, and around 4000 civilians alike, in an act of barbarity which led him to famously describe his soldiers as "the scum of the earth."

Trends in North America c. 1750–1900

In North America, forts were usually constructed from timber rather than stone, though Quebec City is the last city north of Mexico to retain its original stone walls, dating from the mid-eighteenth century, largely intact (the British modified the French walls after Wolfe's victory on the Plains of Abraham, outside the walls, in 1759). It was, however, smaller forts rather than walled cities that were the norm in North America, including what was to become Canada, following the defeat of the French in the French and Indian War of 1754–1763 (known as part of the Seven Years War in Europe). These forts provided footholds on the European frontier as colonists expanded their territories further west and were to provide the focus of conflict first between the French and the British, and then the British and Americans during the American Revolution, which in part grew out of the previous conflict.

Given the longer history of historical archaeology in the USA and Canada, largely due to the colonial character of these late-forming nations and the more recent unwillingness to disturb potentially earlier indigenous sites, it is no surprise that these complex structures have provided a particular focus for archaeologists. Perhaps the most famous of these is among the very earliest. The first archaeological evidence for Jamestown, the site of the first European settlement and fort, in the form of weaponry and ironwork, was ironically uncovered by Confederate troops building fieldworks on the island during the American Civil War. Major excavations in the mid- to late

twentieth century have provided a rich body of evidence for life and death among the first settler communities and also their relationship with Native Americans, which at times was a conflicted one (Kelso 2008). Remains of postholes marking the palisades from which the first fort was constructed have shown a simple triangular plan, with circular bastions in each corner. Of note in the present context is a large assemblage of weaponry and armor, a lot of which was recovered from a well. Much of this equipment, including breastplates, helmets, musket rests, and pike heads, was already well out of date when it was issued from the royal armories for use by the expedition, which perhaps suggests that it was not regarded as a mission likely to succeed. The abandonment and recycling of some of this equipment, including heavy body armor, indicates that it was more of a hindrance than a help when fighting the local inhabitants, in periodic conflicts climaxing in 1622 when 200 colonists were killed. As such, the assemblage provides early evidence for the difficulties inherent in colonial warfare and perhaps even an attempt to adapt to what we would today call asymmetric warfare.

By the mid-eighteenth century, American forts were generally modeled on the Vauban model; though these were usually simpler in plan than their European antecedents and although timber was a popular building material, the larger forts, such as Fort Ticonderoga, included substantial stone elements. As European settlements spread further west and the influence of European powers subsided, most obviously after the American War of Independence, fort design also began to demonstrate variation from the Vauban form in part because protection against artillery became a lesser concern. Simpler, square forts were more common on the Western frontier, just one example being Fort Union, a bison fur trading post in North Dakota, occupied in 1828–1867 (Matzko 2001). As ever, it is difficult to make generalizations, with each fort demonstrating variation based on resource availability, location, architectural preference, garrison size, etc. Despite this, and largely thanks to Hollywood, the "wild west" stockade fort has become an icon of American history.

Although they had an obvious role in defense and conflict in general, colonial forts in the Americas and elsewhere were also an important focus for settlement and trade, and archaeological research based on these sites has made an important contribution to our understanding of social relations among colonists and between colonists and indigenous peoples, with houses (civilian as well as military barracks), sutling houses (stores), and trading posts, all commonly associated with the larger forts (Starbuck 2010). Studies of artifact distributions and food refuse have allowed archaeologists to examine the various ways in which different social and ethnic groups negotiated their place within what could at times have been hostile environments. A typical study is an analysis of military tablewares from 1760 to 1830 from sites in Canada, largely based on a rich assemblage of ceramics from Fort Beauséjour in New Brunswick (Sussman 1978). This suggested that British line regiments chose popular forms of design and pattern as they were more likely to be available in bulk and readily replaced, which in turn led to a number of regiments choosing to use the same ceramic types in the mess. Analysis of building materials from the Fort at Crown Point, New York, built in 1759 (Feister 1984), has demonstrated that even at a wilderness outpost the difference in social standing between officers and men was marked architecturally, here through the use of more expensive materials in the flooring and fireplaces in the officer's barracks than was the case for the accommodation built for other ranks.

The Mid- to Late Nineteenth Century

Military technology, which was always an important factor influencing the evolution of fortifications, saw to it that dramatic changes were again evident by the mid- to late nineteenth century, when further increases in the efficiency of artillery and firearms created the first indications of trench warfare during the American Civil War. The advance of Empire, particularly under the British, also saw an upsurge in the construction of forts across the globe, in places such as India and Africa, and again European patterns were to dominate. In some cases fortifications were makeshift, constructed in a hurry to defend against attack, usually from technologically weaker indigenous peoples. Such was the case at Eshowe, in

Zululand in South Africa, where after a British invasion in January 1879 a fort was constructed around a Norwegian mission station (Pollard and Banks 2005). Captain Wynne, a Royal Engineer officer, integrated well-tested features of European forts, such as the caponnier, within a structure which also demonstrated a good deal of initiative in the face of limited sources and harsh local conditions – including loopholing the church so that rifles could be fired from cover and using biscuit boxes covered in earth to create ramparts (Fig. 2). Today these ramparts with external ditch still stand, and geophysical survey and excavation has identified structures within, including the mission church, from which the iron window frames were removed by Zulus after the siege so that the metal could be recycled (Pollard and Banks 2005).

European military engineers were also in demand in foreign parts outside the Imperial sphere, including Paraguay in South America, where for instance in the 1860s the despotic leader of Paraguay, Francisco Solano Lopez, contracted a Colonel Thompson, along with British railway engineers, iron founders, and surgeons, to supervise the construction of forts and linear defense systems in advance of the catastrophic, but outside of South America little known, War of the Triple Alliance, which between 1864 and 1870 pitted Paraguay against the combined might of Argentina, Uruguay, and Brazil. The remains of these earthwork fortifications, which like those of the American Civil War were to presage the trenches of the First World War, can still be seen today in the south of the country, where urbanization has not had a chance to erase them. Limited archaeological assessment has suggested that these sites have the potential to tell us much about this conflict and the people who fought it (Pollard 2006).

More basic types of fortification are also known, including the *sangar*, a word originating from the nineteenth-century British experience in the North West Passage and in Afghanistan, and referring to stone breastworks and still used today by the British Army and others to describe small-scale defensive structures usually constructed from sandbags. Archaeological survey has identified one of these structures on the battlefield of Isandlwana, fought in Zululand on 22 January 1879. During the battle, which was a resounding victory for the Zulus, a British soldier created a barricade by piling rocks between two boulders; metal detector survey recovered five Martini Henry cartridge cases from the ground just behind the sangar, from where the soldier had fired on the advancing Zulus, probably just before retiring back to the camp area with the rest of the force, where it is likely he met his death. A rare example of fieldworks surviving on a British battlefield is rock-built *sangars* constructed by Spanish troops during the battle of Glenshiel, fought by Jacobite

Fortifications, Archaeology of, Fig. 2 Contemporary drawing of interior of fort at Eshowe by Lt. Knight of Buffs. Note loopholes under eaves of church roof

forces, supported by the Spanish, against government troops in 1719. Several of these structures are still to be seen on a hilltop position in the glen in an area which because of their presence has been protected as a scheduled monument (Fig. 3).

Another category of makeshift fortifications relates to the defense of buildings, either during a siege or battle. The British fort at Eshowe could be taken as an example; however, this was more of a fort built around a mission station than an attempt to fortify the mission station itself. The defense of Rorke's Drift, which took place on the same day as the battle of Isandlwana, is a better known example of modification, with the mission buildings linked with defensive breastworks which themselves were ad hoc, with biscuit boxes, mealie bags, and wagons utilized. These temporary palisades leave little if any archaeological trace, as they are entirely removed after the fighting has ceased, but the remains of the buildings at Rorke's Drift, one of which was burned to the ground in the battle, have been subject to excavation (Pollard and Banks 2005). Other examples include the Alamo, where American irregular troops fighting for Texan independence from Mexico fortified a Spanish mission station. Archaeological excavations have provided some idea of how the defenses were constructed, with trenches not really fitting with the popular image of the defenders standing on walls and makeshift ramparts, though these were also utilized (Ivey and Fox 1997). Some buildings have been subject to the minimum of modification, no matter how rapidly executed, prior to them providing effective defense against attack. A good example of this is the farm complex of Hougoumont, which during the 1815 Battle of Waterloo was defended by British and Allied troops against repeated French attacks (Paget and Saunders 1992). This was only possible thanks to walls and gates which linked various buildings around a courtyard, thus providing a ready-made fort. Loopholes were created and parts of the roof removed to allow sharpshooters a high vantage point, but for the most part the building was left unmodified. Some archaeological excavation has been carried out on the site, but this was merely geared toward uncovering wall bases for display; as yet a full academic program of recording and investigation has to be instigated.

Finally, it was not just Europeans who constructed forts during many of the colonial wars that characterized the rise and fall of the age of Empire. In the 1840s the Maori of New Zealand went to war with the British Empire and used their traditional forts, multi-vallate

Fortifications, Archaeology of, Fig. 3 Stone sangar built by Spanish troops on hilltop at Glenshiel from 1719 Jacobite Rebellion

palisaded settlements often located on terraced hill tops and known as Pãs, to great effect, even using tunnels to evade the enemy and execute ambushes. Archaeologists have recently adopted these indigenous forts as ethnographic parallels to much earlier structures in Europe, namely, Iron Age hillforts, which although built 2000 years before the nineteenth century Pãs share some similarity in form and perhaps function (Armit 2007). Another example of non-European forts which were utilized in defense against the forces of Empire was the Taku forts in China, with some of them built specifically to defend against incursions by the Western powers. The forts saw action during the Opium wars of the 1850s and 1860s, when they were assaulted by British, American, and French troops, and although they put up stiff resistance, they ultimately fell due to superior firepower, the same being the case for forts stormed by a multinational force during the Boxer Rebellion of 1899–1901. Most of the forts were dismantled in the nineteenth century, but two of them, the Hai and Dagu forts on the banks of the river Haihe, have been renovated and serve as visitor attractions.

First and Second World Wars

It was the First World War (1914–1918), especially on the Western Front in Europe, which saw the evolution of trench warfare on an epic scale, as both sides fell into a stalemate following the halting of the German advance by French and British armies. Thousands of kilometers of trenches were dug by both sides, with the no man's land between them sometimes being just a few meters wide. The Germans, who generally managed to occupy more advantageous higher ground, even if it was a ridge line at a few meters altitude, prior to the stalemate, also integrated concrete pillboxes into their trench systems, which provided protection against shell fire and often served to threaten Allied assaults from the rear once they had successfully pushed through several lines of trenches. This defense in depth was a key feature of the development of German trench tactics. The ancient arts of mining beneath enemy fortifications in order to destroy them from below were reintroduced and updated thanks to new types of explosives, which could kill hundreds of men in a single detonation from deep underground. Ultimately, it was the Allied adoption of a combined arms approach, infantry supported by tanks, aircraft, and targeted artillery, late in the war which turned the tide and pushed the Germans back to secondary defensive systems such as the Siegfried line.

First World War archaeology has developed over the past decade and been given new impetus due the last veterans of the war passing away (Novotny 2009). Trenches have provided an obvious focus, and an increasing number of projects have demonstrated that archaeology can shed new light on a conflict which might be thought to be adequately covered by a wealth of photographs, maps, war diaries, and even moving pictures (Fraser and Brown 2007). Archaeology has allowed archaeologists to study this vast, industrial conflict on a micro- and personal scale, and some projects have demonstrated that archaeology can provide insights into aspects of large-scale battles, which have not been recorded in the historical record. An example is the previously undocumented construction of a new communication trench by German troops in advance of the Australian attack in late September 1918 at Mont St Quentin on the Somme. The previous trench was deeper but ran in a straight line rather than in zigzag (Fig. 4) and thus placed men moving along it at greater risk from incoming artillery fire.

In the years following the First World War, the devastated landscape of France and Belgium was repaired and the trenches backfilled. Thousands of laborers were employed on the task, including many Chinese "coolies," and farmers were paid cash for every meter of trench they filled in. Today, there are relatively few original sections to be seen, though bands of chalk running across plowed fields in the Somme are a giveaway of their location. Exceptions are areas of woodland, within which silted remnants of trenches escaped backfilling as they are not on agricultural land. This is the case at Mont St Quentin, where the trench lines can still be seen as linear depressions running through the floor of the wood, in which double-trunked trees are said to be the result of shell damage and then recovery.

Fortifications, Archaeology of, Fig. 4 Topographic survey of German communication trenches at Mont St Quentin, Somme, France. Shows original trench (*lower*) and later zigzag version (*upper*)

In addition to temporary field fortifications, permanent concrete built forts and defenses became a feature of the twentieth century, though the origins of what were sometimes subterranean complexes have their antecedents in the forts of the nineteenth century (including coastal artillery positions in the UK and USA). Advances in gunnery and shell penetration and the need to provide interlocking fire brought about the introduction of underground magazines, with elevators to bring up propellant and shells to the guns mounted in surface batteries. The pop-up gun, which could be loaded under cover and then raised to be fired, was a good example of how in the late nineteenth century artillery was being developed for incorporation into forts rather than fortifications being built around guns. The dominance of artillery on the battlefields of the Western Front eventually meant that there was no safe place on the surface, not even in trenches, and so deep dugouts were constructed to accommodate men in their off-duty hours 15 m or more underground (as previously mentioned, the Germans tended to prefer pillboxes to deep dugouts). Several of these structures have been excavated, and, in some, the water-logged conditions (Fig. 5) have demonstrated incredible levels of preservation not only in the wooden structure but also in the objects surviving (Barton et al. 2005).

Fixed fortifications could be found wanting, as was the case with the Maginot Line, a series of underground magazines, barracks, communication hubs, and tunnels, supported by an underground railway and linking guns enclosed in armored cupolas on the surface. This impressive structure was built after the First World War across the French-German border to prevent future incursions by the latter. In 1940 the Germans, utilizing Blitzkrieg tactics honed in Poland, simply sidestepped the defenses and went around them. The Germans were however to place much store on an impressive range of largely concrete built fortifications known as the Atlantic Wall, which stretched along the western seaboard of Europe.

Fortifications, Archaeology of, Fig. 5 Stairway in British deep dugout known as Vampir, near Ypres, Flanders, Belgium. Structure has just been drained, hence sludge on steps

These installations included massive bunker-type emplacements which housed 15- and 16-in. guns capable of hitting the English town of Dover nearly 50 kilometers away across the English Channel. Slave labor was utilized in the construction of these fortifications in a program supervised by Organisation Todt, the civil and military engineering wing of the Third Reich also responsible for the German system of freeways known as the autobahn.

In the lead up to D-day on 6 June 1944, the Allies in Britain developed various technologies for overwhelming these defenses, including a series of specialist armored tanks and other vehicles, known as Funnies, which were variously capable of swimming ashore, laying tracks over soft sand, clearing mines, and planting explosive charges on heavily fortified positions. These were tested against replicas of the German defenses, the most impressive of which can still be seen on an isolated moor not far to the north of Stirling in Scotland (Fig. 6). This striking reminder of the effort put into D-day is protected as a scheduled monument and is likely to be subject to full archaeological recording at some point in the future. Despite heavy losses on some of the invasion beaches, D-day was a success, and the major problems occurred once the Atlantic Wall had been negotiated, when the Allied advance was slowed due to the enclosed nature of the French landscape and the effective deployment of German forces, especially their tanks. In a move similar to the German treatment of the Maginot Line, the heavily fortified gun emplacements were simply bypassed and isolated, most of them finally surrendering to the Allies after some resistance in September of 1944.

Hindsight is a wonderful thing, and today we are comfortable in the knowledge that Hitler's Germany and the Axis powers lost the Second World War. Obviously, this was not the case in the early months and years of the war, when prior to the intervention of the USA, Britain alone continued to resist. For a time, German invasion of mainland Britain seemed inevitable, and so in order to defend against it, a wealth of defensive fortifications were constructed. These included stop lines around major cities such as London, where ditches were dug and concrete bunkers built in order to break the momentum of a German advance. The pillbox, small concrete boxes, mostly built to accommodate just a handful of men armed with rifles and machine guns, became a ubiquitous feature of the British landscape. Today, they can still be seen covering roads, railways, and bridges, sitting on high ground where they had good fields of fire or covering the approach to a crossroad. In addition, there were coastal gun installations, underground headquarter complexes, airfield defenses, subterranean hospitals, and all manner of inventive devices. The Tett turret for instance was a one-man pillbox, really nothing more than a pipe sunk vertically into the ground with a rotating concrete turret sitting on the ground surface. Not many were put into service, largely because they were a defense of last resort; for once in them there was little hope of escape once combat commenced. Several of these were located during an archaeological

Fortifications, Archaeology of, Fig. 6 Replica section of German Atlantic Wall used for D-day training, Sheriffmuir, Scotland

survey of Hornchurch airfield in Essex and have since been integrated into a heritage walk around the remains of the old airfield which saw heavy service during the Battle of Britain (Pollard and Oliver 2002).

Post–Second World War Examples

The post–Second World War nuclear age brought about another shift in the nature of fortifications with the destructive power of the atom bomb which encouraged the move to deep protective structures, for both the defense against nuclear strike and the accommodation of missiles in fortified silos. With nuclear limitation and the demise of the USSR, many of these sites have fallen into disuse and to a degree have been accepted as elements of our cultural heritage (Cocroft et al. 2005). Field fortifications of a more traditional nature did not however disappear, and entrenched firebases became a key element of the failed US insertion strategy in Vietnam where helicopters, aerial bombardment, and artillery provided support for these isolated strongpoints deep in enemy-held territory. Following the invasion of the Falkland Islands in 1982, Argentine troops built great numbers of small bunkers or sangars from rocks, turf, and timber, one reason being that the ground is so wet that the digging of trenches is all but impossible. In Iraq and Afghanistan, the modern equivalent of the firebase can be seen in the form of the many strongpoints, depots, and fortified camps which provide protection for US, British, and other forces engaged in these theaters. There can be little doubt that at some point in the future these conflicts, raw and alive as they are at present, will attract the attention of archaeologists. Some of these sites, such as the tunnels dug by the Viet Cong to provide protection from American aerial bombing and artillery fire and also as a means of springing ambushes, have already become a popular visitor attraction and perhaps serve as an indicator of the potential for other modern fortifications and installations as tourist-friendly heritage sites.

Future Directions

The foregoing has attempted to provide a basic overview of the many different types of fortification, both defensive and offensive, which have played a role in various conflicts across the globe in the postmedieval period (1500–present). Although it has not been possible to provide an exhaustive survey, it is hoped that the wide range of variation in form and function is apparent,

given a modest suggestion of the sorts of information which the archaeological analysis of these structures can provide.

Fortified Homesteads

Nicolas Grguric
Adelaide, Australia

Introduction

The fortified house represents a subclass of vernacular architecture. These are civilian buildings, into which certain architectural features have been incorporated in order to make them more defendable. Fortified houses are typically a product of frontier

conditions and can be found in as widely separated contexts as seventeenth-century Ireland (Nunan 2006), nineteenth-century Australia (Grguric 2007), and twentieth-century South Africa (Bremner 1999) to name a few. On face value these structures were built to protect the occupants from attackers. However, because fortified houses directly reflect the needs of the builders in their own particular context, such structures also embody the builder's emotions at a particular time and place. In particular, they represent physical manifestations of fear on the part of the builder. This remains so, whether one considers the fear to be justified or not. Furthermore, these structures are often imbued with a powerful mythology connected to their defensive nature which plays into notions of settler identity construction. Because fortified houses manifest themselves in numerous contexts across the globe, there is ample potential for comparative analysis to be made between the occurrences of this phenomenon in different frontier environments.

Definition

A fortified house is a dwelling built by civilians which incorporates one or more architectural features, designed to render the building more defendable in the event of an attack. This definition excludes purely ornamental features such as decorative crenellations or towers and refers specifically to buildings whose defensive features were included in response to a perceived threat. As it is used here, this term also excludes structures built by the military and other government authorities. Fortification can be defined as "all dispositions made which allow a defending force to defend a position to its advantage" (Lafferty 1973, quoted in Kenzle 1997: 201). The most common method used to make houses more defendable was the inclusion of one or more small apertures in the walls through which the occupants could observe and fire weapons through while being relatively protected (Grguric 2007: 84). The correct term for such an aperture is "embrasure" (Johnson 1976: 268). Embrasures could take the form of elongated slits with outward-angled sides or simple square or rectangular perforations in a wall. Generally, fortified houses are associated with frontier environments and were built by colonists/settlers as a response to conflict with Indigenous peoples (Figs. 1, 2, and 3).

Historical Background

The architectural historian, J.M. Freeland, realized the significance of buildings as "original historical documents," noting that "[a] country's architecture is a near-perfect record of its history. Every building records, describes and explains the time and the place in which it was built" (1968: Preface). Fortified houses represent both real and perceived conflict between invaders and the invaded. They are significant and unique, in that they are standing testimonials to historical periods of fear and conflict. Research into these structures and their past and present social context, contributes to a greater understanding of frontier architecture as well as to frontiers in general.

The modification of material culture as a result of cross-cultural contact is an area which has been investigated by archaeologists to some extent (e.g., Rubertone 1994; Hoagland 1999; Bender and Winer 2001). At the 1999 World Archaeological Conference, a workshop was held on the topic of "The archaeology of culture contact in Australia and beyond" (Harrison and Paterson 1999). One of the sessions discussed "the use, modification and identification of material culture sites in the archaeology of culture contact." However, one factor influencing the material culture contact which was not considered was that of fear. Fear is an all-important factor in the construction of fortified houses because it was this emotion that caused their construction.

In his PhD dissertation, Nicolas Grguric identified fortified houses as a sub-category of Australian vernacular frontier architecture (2007). Grguric found the typical Australian fortified house took the form of a vernacular dwelling of British heritage, but with the addition of one or more embrasures in its walls. In addition to testing and evaluating the actual functionality of these structures, Grguric also investigated the role local

Fortified Homesteads, Fig. 1 Rear view of the "men's hut" at Central Outstation, Eyre Peninsula, South Australia, showing three evenly spaced embrasures positioned along the wall, built to provide defense against potential Indigenous raids. This fortified house was built in the mid-1850s for sheep station workers. (After Baillie 1978: 134)

histories attached to these sites played in the mythology of settler society identity construction (2010: 49–67). He found in the buildings attached to these stories a physical manifestation of what historian Rick Foster described as, "[t]he tension between the desire to reveal and the imperative to conceal – the pride in the hardship and danger of 'winning the land' set against the fear of revealing too much" (2009: 68.13). Some local histories pointed out that a certain building was fortified for defense against Aboriginal attack, whereas others omitted this aspect of the site history altogether (Grguric 2010: 62–65). Grguric noticed a trend in the stories attached to these buildings to portray the settlers as victimized by Aboriginal people while omitting any explanation as to why conflict was occurring or any wrongdoing on the part of the settlers. This selective remembering of the history attached to fortified houses has made them into monuments that serve to justify the colonizer's occupation of the land as won through suffering.

Joe Nunan's study of seventeenth-century fortified houses of County Cork in Ireland has provided a comprehensive analysis of defensive, architectural, and social aspects of these structures (2005). Irish fortified houses formed a transitional phase of architecture that bridges the gap between the medieval Irish tower house and the unfortified country manor house of the late seventeenth century (Nunan 2006: 1). Fortified houses were built to protect the Irish elite from banditry, cattle raids, or attack during rebellion. They took the form of a substantial dwelling with embrasures and other defensive architectural features taken from medieval castles. In later versions, a fortified walled enclosure called a "bawn" incorporating embrasures and corner towers became the primary fortification, with the house incorporated into the bawn (Nunan 2006: 2). As well as addressing the need to defend the property and lives in turbulent times, Nunan believes the construction of fortified houses by the Irish elite represented their desire to modernize and Anglicize (2006: 1).

Blair St. George investigated the transplanting of the Irish fortified house style into frontier New England in the United States (1990). He analyzed the architectural sources upon which the English

Fortified Homesteads, Fig. 2 Interior of the "men's hut" at Central Outstation, Eyre Peninsula, South Australia, showing the position of one of the embrasures, located at a suitable height through which to use a firearm. (After Grguric 2007: 149)

settlers of New England drew when they constructed this enclosed, courtyarded settlement form in a new environment. Two such houses are focused on one which still stands, known as the "Whitfield House," and another which is only known from a contemporary plan. The Whitfield House, which included an embrasure for a small cannon in its upper story, also provides an example of the use of archaeological excavation to investigate a civilian-built defensive structure on the US frontier. In this case, excavation suggested that the house may well have formed part of a larger enclosed complex, such as a bawn (Langley 1982).

Turning to the East Cape of South Africa, a region settled by Anglo-Europeans in the late eighteenth and nineteenth centuries, Margot Winer provides some examples of the influence of fear on civilian architecture. Winer studied changes in vernacular architecture in the small British settler village of Salem on the East Cape (2001: 257–271). Winer identified four phases of frontier-influenced modifications to the vernacular architecture which she termed "Architecture of Coping (1820–1823)," "Architecture of Identity (1823–1832)," "Architecture of Affluence (1832–1860)," and "Architecture of Fear (1835+ recurring)" (Winer 2001: Fig. 15.1). The changes in architecture that this final phase displayed were brought about by widespread and devastating attacks upon settler property and the lives by the Indigenous Xhosa people during what are known as the Cape Wars. This phase was characterized by the incorporation of defensive architectural features into older forms, the construction of new dwellings with embrasures, and other defensive techniques. For example, previously built structures, such as farmyard walls, which were usually seen only as symbolic perimeter markers and barriers to livestock, were modified by the digging of deep ditches on the outside to convert them into fortifications. Newly built farms were constructed so that all the buildings and livestock areas were protected by high walls with embrasures for defense. Also, hedges of brush and other thorny plants were used as protective barriers (Winer 2001: Fig. 15.1, 266).

Fear of the kind felt by the colonial settlers of the seventeenth to nineteenth centuries and its subsequent visibility in civilian architecture can even be seen in the modern era in the example of fortified houses in Johannesburg in South Africa. Here, European people's fear of crime has resulted in the construction of heavily fortified houses and communities, using razor wire, high walls, and sophisticated surveillance systems (Bremner 1999: B2).

Key Issues/Current Debates

Where oral and local histories associated with such sites refer to fortified houses as having been built for defense against Indigenous people, this goes to the heart of the controversy surrounding the history of frontier conflict in Australia. The

Fortified Homesteads, Fig. 3 Plan of the "men's hut" at Central Outstation, Eyre Peninsula, South Australia, showing extrapolated fields of fire provided by the embrasures. The dark gray-shaded portion denotes intersecting fields of fire. The black outline represents a subsequently demolished building. (After Grguric 2007a: 166)

source of the controversy is the fact that such stories highlight a history of violent race relations. This has been a contentious issue to many, as evidenced in the ongoing public debate in Australia which has become known as the "history wars" (see Macintyre and Clark 2004). The issue is sometimes all the more sensitive in rural areas where descendants of the pioneer settlers are still associated with the land their forbears wrested from its Aboriginal owners. In this case, Stanner's culture of silence (1974) may exist, manifesting itself in an attempt to deny or cover up stories of frontier conflict in order to prevent the memory of pioneering ancestors being sullied with charges of racial violence (Haggis 2001: 92).

Historian Robert Foster has shown that, although denial (or "forgetting") was a characteristic of the national identity construction narrative, when it comes to local history, "misrememberance" is a more common characterization (2009: 68.2). During the process of constructing social identity, elements of history can be forgotten, excluded, altered, or added. In terms of fortified houses, this translates into the creation of histories about a structure's defensive use. In his research into fortified houses in Australia, Grguric found that some believed that a particular structure was built for defense, while others did not (2007: 3). It is important to investigate why such opposing views of history exist, as they may tell us something about the ways in which communities remember their past, and why some memories are privileged, while others are forgotten, denied, or even hidden. In a sense, fortified houses can tell of a hidden history. This has considerable political relevance because of what it can tell us about race relations on the frontiers and modern relationships between Indigenous and non-Indigenous communities today that rest on these foundations. For example, structures which were built defensively out of fear of Indigenous attack could stand as physical monuments to the fact that Indigenous resistance was strong enough in that area to cause the invading colonists to take such precautions and that the settlers feared what they could not understand. Moreover, the fact that colonial settlers found it necessary to fortify their structures could illustrate the fact that the land was taken by force from its Indigenous owners. As Lydon and Ireland argue,

"heritage" is actually "an active process of identity formation and so has become the arena for contesting the form and content of national identity" (Lydon and Ireland 2005: 3).

The confusion that surrounds examples of fortified houses also stems from the peculiar nature of these buildings. They are not usually purely defensive structures such as a fort, but instead they served multiple roles. Therefore, what would usually be a diagnostic element of use as a fortification, such as a narrow slit in a wall, may not necessarily have functioned that way and may have served an entirely different purpose. This issue is not, however, limited to the Australian context; other studies of civilian defensive architecture in different contexts have had to grapple with the same problem. For example, Blair St. George, in his investigation of the seventeenth-century Whitfield House in Connecticut, USA, found that there was disagreement over the existence and function of what he argues was a cannon embrasure located in an upper wall of the house (1990: 265). Blair St. George convincingly argued that it was in fact a cannon embrasure. One of the ways he supported his interpretation was by comparing it to several contemporary fortified houses in Europe and Ireland which also have cannon and small arm embrasures (Blair St. George 1990: 265–6, 276–7).

Future Directions

There are internationally observable patterns in the relationship between settler societies, fear, race relations, and the resulting influences on architectural material culture. This provides opportunities for cross-contextual analysis. Using such an approach, fortified houses and the conditions that gave rise to their construction have the potential to provide transnational perspectives of the processes involved. This allows one to understand contact and colonialism using a global approach, not just focusing on particular times and places in isolation.

By way of example, the Australian frontier was characterized by often intimate cultural intermingling, both peaceful and violent (Denholm 1979: 40). Although this kind of intermingled frontier is characteristically Australian and was one of the main formative factors of the nature of Australian frontier conflict, a comparable situation has been pointed out by Winer in relation to the East Cape frontier in South Africa at a similar period (i.e., 1779–1870) (Winer 2001: 257–9). Winer's observation that "[t]he practical, logical *modus vivendi* bred of proximity, intimacy, familiarity and mutual convenience was co-operation and conflict simultaneously" (Winer 2001: 258–9) could equally be said for the Australian frontier (e.g., Critchett 1990: 23). Therefore, it is probable that given the similar character of the different frontiers, one can expect to see similarities between them in the kinds of material culture produced, its meaning and function, and also in the myths produced around these frontier sites. In this example, Winer identified very similar processes in the incorporation of defensive architectural techniques into civilian buildings in the East Cape of South Africa as Grguric observed in Australia (Winer 2001: Fig. 15.1; Grguric 2007: 287–291).

Forum

Francesco Marcattili
Dipartimento Uomo e Territorio Sezione di Studi Comparati sulle Società Antiche, Università degli Studi di Perugia, Perugia, Italy

Introduction and Definition

A *locus celeberrimus* composed of an often-rectangular space delimited by religious and administrative buildings, the forum constitutes the institutional, commercial, and monumental center of a Roman city (Gros 2001: 228–259, with bibliography). An inaugurated area, ritually delimited as a *templum augurale* to be able to host, as in the *Saepta*, popular meetings and electoral assemblies in particular, the forum is the site devoted to the essential social and public activities of colonies and municipalities alike: in fact, the chief ritual celebrations of the community are either observed in the forum or passed through it. Laws are promulgated in the forum, trials conducted, and justice administered. Just as in Greek *agorai*, commercial transactions are often conducted in the forum. Forum squares equipped with temporary wooden stands (public *fori*) would be the site of games (*ludi*) or gladiatorial contests in the presence of the populace (Liv. 41.28.11).

During the late Republican period, the need to satisfy the multipurpose uses of the forum seems to have inspired the emergence of a number of different building typologies and/or complexes, each with a specific functionality organically

linked to the forum space. These included the architecturalization of the curia-*comitium* system (Balty 1991), present in the Forum Romanum since the sixth century BCE as an area for meetings of the Senate and for the *comitia curiata* (Coarelli 1983; Coarelli 1985). Certain Latin colonies in Italy dating to the third century BCE reproduced this architectural form. The *atria publica* were venues of both public and religious activity provided with shops (*tabernae*) for commercial use. The *basilica forensis* was a monumental building with a complicated usage; the building could accommodate judicial, administrative, and financial activities. The *tabularium*, a building mainly used as an archive (*tabulae publicae*), faced the Forum Romanum from the slope of the Capitoline hill, in Rome's case. Lastly, the *macellum*, a structure with a peculiar plan, served as a market for the sale of meat and fish.

Surrounding many of these secular buildings, often placed in emphatic positions, one could find the monumentalized forms of preexisting sacred sites linked to the venerable traditions of the city's past (and often its origins). In the case of subjugated cities or territories, these cults were always adjusted according to the rules of *interpretatio romana* (e.g., Hercules of Alba Fucens; the Greek divinities of Paestum; the Iuppiter cult of Pompeii). Otherwise temples and shrines (*sacella*) for newly established cults, as demonstrated by the *Capitolia* and the numerous temples (*aedes*) dedicated to members of the Imperial house, constituted a clear manifestation of Roman politics and power, and consequently of the loyalty of the municipal élites towards the central government.

This cumulative function makes the forum and its buildings the privileged site for individual and collective, private and public, profane and religious meetings. Accordingly, in such a frequented place the most relevant commemorative and honorific monuments of the city were displayed and adorned with both images and inscriptions that promoted the military exploits and the munificence of generals, politicians, and notables. It has been correctly pointed out that the forum is:

> "an authentic *monumentum*, a site of memory", "in which all of the symbols of municipal dignity are concentrated and around which the next generations, aside from their juridical status, acquire or enforce the awareness of belonging to a community." (Gros 2001: 228)

Arches, trophies, columns, and honorific statues constitute the usual architectural and sculptural adornment of the open central area. From the second century BCE onwards there exists a tendency to use framing devices to both regularize and emphasize the longitudinal perspective of the forum and its buildings. This included the use of side streets and gates and, in particular, the *porticus*.

Key Issues/Current Debates/Future Directions/Examples

The city of Rome's so-called Imperial *fora*, a series of majestic squares bordered by arcades, began with the Forum of Julius Caesar and, with the exception of the Forum of Trajan, were dominated on their short sides by temples dedicated to the tutelary deities of the dynasty. These forum complexes doubtlessly represent the culmination of this arc of monumental and ideological development. These Imperial *fora* were configured as complexes with celebratory and commemorative purposes that prevailed over the institutional and commercial functions. The spatial progression and the monumental evolution of the Forum Romanum, but also of the different colonial and municipal *fora*, coincide also with the history of the conquest of public power over private property. It is a phenomenon that emerged as another sign of the gradual and unavoidable crisis of Republican society, already underway in the second century BCE with the Roman triumphs in Greece and in the eastern Mediterranean and the consequent diffusion of the multiform manifestations of *luxuria Asiatica* (Pollitt 1978). The residences of the local aristocrats normally occupied many central and/or contiguous blocks of a city's layout until the final two centuries of the Republic when these residences often were expropriated for the extension of the forum spaces and for the

creation of new civic and religious buildings. For example, the luxurious house (*domus*) that Publius Cornelius Scipio Africanus had built facing on to the Forum Romanum was razed by Ti. Sempronius Gracchus in order to make way for the construction of the Basilica Sempronia (Liv. 44.16.10). Similar is the case of the land on which the Forum of Julius Caesar was built after Cicero purchased it in 54 BCE, under the mandate of his then-friend Julius Caesar, for the sum of 60 million sesterces (Cic. *ad Att*. 4.16.8). The latter operation was accompanied by the complementary, firm will to unhinge "the old Republican symbology" (Coarelli 1985: 237) and which culminated, in fact, in the demolition of the Curia and some of the monuments of the ancient *Comitium*.

In the articulated process of monumental and architectural development of forum squares, it is possible to distinguish at least three crucial moments, documented not only by means of historiography but also by decades of archaeological investigation. The phase of middle Republican colonization that followed the dissolution of the Latin League in 338 BCE (Gros and Torelli 2007: 165–181) coincided with the final decades of the fourth century and the early decades of the third century BCE. This was a first, crucial moment in the conceptualization and realization of both the space and the architecture of forum squares, as demonstrated by the excavated colonial sites of Fregellae, Alba Fucens, Cosa, and Paestum. These middle Republican sites, at least, seem to adopt urban and architectural solutions in faithful conformity and in full synchronicity with the city of Rome (Torelli 1999). As documented by a series of pits discovered at the margins of the squares of these cities, the *fora* created by the new colonies were founded, as in Rome, not only according to augural doctrine so that they could serve as *saepta* (Torelli 1991), but also in keeping with the process of the *imitatio Urbis*. In Cosa, for example, the combination of the citadel (*arx*), the sacred road (*via Sacra*), and the forum may be seen to imitate the urban situation at Rome (Brown 1980; Brown et al. 1993).

The circular *comitium*, perhaps inspired by the *ekklesiasterion* of Magna Graecia and Sicily, preserves in its quadrangular enclosure its original nature as *templum* following the Italic tradition. It is significant to note that this situation is present in all four of the colonies mentioned above as a reproduction of the Roman *Comitium* that gained this particular configuration from a reconstruction of c. 263 BCE (Coarelli 1983: 145–153). On the other hand, the *atria publica* with *tabernae* investigated at the margins of Cosa's square (Brown et al. 1993: 57–106) are reproductions of the analogous buildings that bordered the mid-Republican Forum Romanum (Welin 1953: 178–219); these are mainly known via the literary sources (*atrium Regium*, *atrium Vestae, atrium Libertatis*, *atrium Sutorium*, *atria Licinia*, *atrium Maenium*, *atrium Titium*). And finally the discovery of a bronze statue of Marsyas in the area of Paestum's forum is perhaps a replica of the statue present in the *Comitium* of Rome since 294 BCE; this demonstrates the deep and faithful accuracy that guided the imitation of urban models, in that it even involved, for political purposes, the reproduction of single statues.

A second important moment in the evolution of the forum is certainly the second century BCE, coincident with Rome's eastern conquests and with the transformation of the institution of colonialism that had fallen into a crisis because of the increasing political and economic demands of the settlers (Gros and Torelli 2007: 181–198). This is the phase of rationalization and monumentalization of the Italic cities, which was made possible thanks to the wider availability of resources and was carried out under the decisive influence of Hellenistic urban planning and architecture. Also in the *fora* the monumental apparatus increased considerably, as they started to include building typologies not previously or substantially well known in the Roman world, such as the *porticus*, the basilica, the *macellum* (market), and sometimes public baths (*thermae*). In many cases, however, the planning and the transformation processes of the period are conditioned by preexisting circumstances and structures that, as demonstrated by the Forum Romanum itself, can significantly scale down the ambitious intentions of regular urban planning.

After the establishment (*deductio*) of a Sullan colony in 80 BCE at Pompeii, an increased degree of regularity in the forum area may be observed.

This took the form of a basilica, the *macellum*, and arcades that were aligned with the axis of Iuppiter temple that was transformed into the Capitolium of the town. These building activities contribute to an attempt to realign the public space on an axis that diverged from that of the preexisting ancient sanctuary of Apollo that stood adjacent to the forum square.

The addition of the basilica and a *forum Piscarium* constitutes the most relevant building integrations of the period in Cosa's forum; in the arcades positioned on the three sides of the forum and in the monumental arch erected at the northwest entrance of the square shortly after 180 BCE, an analogous desire for spatial and prospective regularization is revealed. In the forum of Alba Fucens, where there is also an attestation for the presence of a statue of Marsyas, a basilica and *macellum* were part of the same phase of construction. As in the previous century, the Forum Romanum remained the model for those realizations of the colonial *fora*. At Rome the comedic playwright Plautus described the Forum Romanum in the final years of the third century BCE and, based on the textual account, it seems that the elaboration of both basilica and *macellum* typologies had begun. These complexes were inspired by an increasing specialization of space and function that, as a matter of fact, replaced structures considered outdated by this time such as the *atria* or the alimentary *fora* (*Piscarium* and *Cuppedinis*). In Rome, in a few years and despite a strong opposition, three *basilicae* were built that not only conferred a certain symmetry at the long side of the forum square but radically changed the organization and the efficiency of the forum space. In 184 BCE the Basilica Porcia replaced the two public *atria* (*Maenium et Titium*). In 179 BCE the Basilica Fulvia-Aemilia was built during the famous censorship of M. Fulvius Nobilior (Liv. 40.51), and finally, in the area of the still visible Basilica Iulia, the Basilica Sempronia was built in 169 BCE (Liv. 39.44). The sumptuous Basilica Aemilia remained for centuries as a commemorative monument of the *gens Aemilia*, showing how, at its best, enduring propaganda was always combined with ordinary functionality (Plin. *HN* 36.102).

This evident inclination for celebration, already present for centuries in the buildings and monuments of the Forum Romanum, was transformed into dynastic glorification under the pressure of the imperialistic tendencies of the first century BCE, as the creation of the Forum of Caesar clearly demonstrates. The complex inaugurated by the dictator in 46 BCE therefore ratifies a new phase of the general evolution of the ideology of forum squares: from this time, not just the successive Imperial *fora* (La Rocca et al. 1995; Packer 1997; La Rocca 2001; Meneghini and Santangeli Valenzani 2007, 2010) but also all of the *fora* of the Italian and provincial centers (Gros and Torelli 2007: 243–392) will be tasked to satisfy the fundamental needs of propaganda and the cult of the emperors and of their families through every public and religious building, a phenomenon that coincides with a phase of gradual "restriction of municipal and colonial powers" (Gros 2001: 237). The structural solutions tested in the Italic territory since the second century BCE, though, will turn out to be perfectly up to date in the new constructions, and they will sometimes be applied in an even more radical way, as clearly shown by the Imperial *fora* (Fig. 1) and, outside of Italy, by the exceptional "provincial *fora*" (e.g., Tarragona) (Gros 2001: 252–255). The width of the squares with arcades, the size of religious buildings, and the tendency towards enclosure are characteristics that had already been proven in Rome in the *porticus* of the Campus Martius. On the other hand, each of the Imperial *fora* is provided with distinctive monumental features, a clear result of contingency, but also of centuries of architectonic progress and intentionally diverse ideological choices. Accordingly, in the Forum of Augustus (42–2 BCE) large hemicycles are added to the porticoes that flank the central temple dedicated to Mars Ultor, elements that were already present in the Forum of Caesar. In the Forum of Augustus the inclusion of an exceptional sculptural program summarized the mythic origins and the history of Rome. Vespasian built the *Templum Pacis* (71–75 CE) on the site of the Republican *macellum* in order to celebrate his victory of the Judean war; it featured the temple with its façade aligned with the lateral arcades that delimited a central area glorified by works of art and gardens. A long and quiet narrow

Forum, Fig. 1 The Imperial fora. (From Meneghini and Santangeli Valenzani 2010: 104, Fig. 2)

square characterized the Forum of Nerva or Transitorium, inaugurated in 97 CE and dominated by a temple dedicated to Minerva. Due to the constraints of the available space it showed very particular arcades, constituted by a colonnade raised close to the walls at the end of the complex. Finally the most revolutionary and extensive of the Imperial *fora*, that of Trajan (107–113 CE), *locus sepolturae* of the *optimus Princeps* and of his wife Plotina, was built between the Quirinal and Capitoline hills after an exceptional program of excavation. Financed with the proceeds of the Dacian campaigns, it was composed of a monumental sequence that included a large square with arcades, two lateral *exedrae*, and the equestrian statue of Trajan; the Basilica Ulpia closed the minor northwestern side of the square and, behind it, finally, stood the Column of Trajan with its two flanking libraries.

In line with the urban models, there are two traditional building types that, more than others, seem to qualify the municipal forum as belonging to the Imperial period. These two are the principal sanctuary of the city, most often axially aligned and dedicated to the Capitoline Triad or to the cult of Roma and *principes*, and the civil basilica, that often closes one of the short sides of the forum and that now, with the disappearance of *comitia*, includes the Curia inside it. Buildings that when located in the same position, one in front of the other on the same axis, divided in the middle only by the regular square with arcades, create the popular system of the forum called "tripartite," which became very common during the Imperial period in the provincial centers (Gros 2001: 242–247). Since the Augustan period, the need to celebrate scenic *ludi* in honor of the dynasties could determine the location of theatres close to the forum temples dedicated to the dynastic cult, as is demonstrated well by the cases of Minturnae, Brixia, and Augusta Bagiennorum.

The forum of Pompeii and the forum of Glanum – one Italic, the other provincial – constitute two optimum demonstrations of the development of public areas reflecting the new needs of Imperial religion and Roman administration. The eastern part of the forum of Pompeii (Fig. 2), already occupied by the temple of the Capitoline Triad and by Apollo's sanctuary in the northern and western sides, is entirely reshaped by the creation of a temple of the *Genius Augusti*, the temple of Public *Lares*, and the building of Eumachia, imitating the *porticus Liviae* of Rome in the Campanian center (Torelli 1998). At Glanum, located in Gallia Narbonensis, the Roman conquest resulted in the obliteration of the Hellenistic public area around 40 BCE; it

Forum, Fig. 2 Plan of the forum of Pompeii. (From Gros 2001: 232, Fig. 247)

was replaced by two temples (30–20 BCE) and by a forum provided with arcades, a basilica, Curia, *tabularium*, and public bath. The growing desire for self-representation on the part of the local élites, ever more greedy for political privileges and for the good will of the Imperial court, led some families to focus their euergetic activity and to invest their own funds in the construction and embellishment of the monumental centers, as happens, for example, in the cities of Dougga and Lepcis Magna in north Africa. The dynamism of three prominent *gentes* (ancient Roman families), together with some preexisting structures, renders quite peculiar the plan and spatial organization of the forum of Dougga in *Africa Proconsularis*. *Domi nobiles* (local nobles) belonging to wealthy indigenous families are responsible, from the late first century BCE, for the realization of the main public and religious buildings of Lepcis Magna, a city that concentrated in the so-called Old Forum the basilica, the Curia, and six cult places dedicated to traditional Punic divinities now side by side with the new Roman divinities (Roma, Augustus, and the Capitoline Triad).

Thanks to the generosity of the locally born emperor Septimius Severus (r. 193–211 CE), the city of Lepcis Magna was provided with a second, monumental forum in the third century CE. The monumentality of the dynastic temple and scope of the wide square bounded by arcades, the impressive basilica built on the minor side of the square, and provided with two mirror hemicycles just as the Basilica Ulpia in Rome, shows one more time the prestige exercised in the monumental center of the *Urbs Roma*.

The Forum Romanum itself would maintain both its charm and some of its ancient functions for centuries, until the construction of the final ancient monument in the square. This final monument was an honorific column crowned with a statue and dedicated to the Emperor Phocas in 608 CE; it remains visible in the Forum Romanum to this day.

Fossil Records of Early African *Homo*

Kes Schroer and Chrisandra Kufeldt
Center for the Advanced Study of Hominid Paleobiology, The George Washington University, Washington, DC, USA

Introduction

Molecular and paleontological evidence suggests that modern humans first originated in Africa as early as 250,000 years ago. However, fossil remains in Eurasia dating to at least 1.8 mya (million years ago) suggest that some of our ancient relatives had already migrated out of Africa by the time modern humans emerged. Thus, the peopling of the world does not begin with modern humans. Rather, the fossil record suggests a long history of previous occupations in Africa and Eurasia.

In this review, we discuss the nearest fossil relatives of modern humans. The fossil species we review include the early members of the genus *Homo*, a group within the broader category of "hominins" (all primate species more closely related to modern humans than to any other living taxon). Early *Homo* likely shared its environment with non-*Homo* hominins such as *Paranthropus*, a taxon with a suite of morphological features distinct from the derived characteristics of the genus *Homo*. When we speak of derived traits in *Homo*, we mean traits shared with modern

humans. In contrast, primitive traits are morphological features shared by all hominins and therefore not unique to *Homo*. Both primitive and derived traits are combined to define the morphology of a fossil taxon. "Taxon" (pl. taxa) refers to a hierarchical category, and although taxon is often equated with species, this is not necessarily correct. "*Homo*" is a genus-level taxon, while our species, *Homo sapiens*, is a species-level taxon. Because it is difficult to establish speciation events for certain in the fossil record, we prefer to use the term taxon and begin by reviewing the definition of the taxon *Homo*.

Definition

What Is *Homo*?

In 1940, Franz Weidenreich proposed the inclusion of several hominin fossils in the genus *Homo* on the basis of their morphological similarities with two well-established taxa of *Homo* known at the time, *H. sapiens* and *Homo neanderthalensis* (Neanderthals). These additional specimens were classified as *Homo erectus*. The addition of a new taxon to the genus *Homo* necessitated an improved definition of the genus *Homo*. In 1950, Ernst Mayr proposed that *Homo* was a genus of modern human-like creatures whose members showed morphological evidence of increased brain size and bipedal locomotion. However, this definition was unsatisfactory, for it would have included specimens belonging to, *Australopithecus*, a different hominin genus established in 1925. Wilfrid Le Gros Clark expanded upon Mayr's definition and provided four criteria for inclusion into the genus *Homo*: a minimum endocranial volume of 750 cc (cubic centimeters), evidence of tool use, evidence of a precision grip, and evidence of spoken language. Additionally, he suggested that derived morphological traits of *Homo* included a cranium with less robust muscular markings, a flatter (more orthognathic) face, a rounded dental arcade with no evidence of a premolar-canine honing complex, smaller teeth, and adaptations for bipedalism.

This description of *Homo* has undergone many revisions and interpretations, especially in light of the discoveries of many more hominin fossils since the 1950s. Some of the modifications to this definition are discussed in the text that follows, but it is important to note that researchers today have the benefit of more fossils and more rigorous phylogenetic methods to assess the evolutionary relationships of modern humans and fossil hominins. One prominent cladistics-based definition describes the crania of members of *Homo* as possessing, relative to *Australopithecus*, a thicker cranial vault, greater cranial vault height, reduced postorbital constriction, increased contribution of the occipital bone to the cranial sagittal arc length, an anteriorly situated foramen magnum, reduced prognathism, narrow tooth crowns especially in the premolars, and reduction in the length of the molar row (Chamberlain and Wood 1987). Another phylogenetic study found only four derived features common to all members of the genus *Homo* – a larger brain, the absence of a nasal sill, reduced temporal lines, and fewer air cells in the temporal squama (Strait et al. 1997). Though there are discrepancies between analyses, definitions of *Homo* are becoming more specific and quantifiable.

In both historic and modern approaches to defining the genus *Homo*, there is a well-recognized distinction between the earliest forms of *Homo* that still share many traits with *Australopithecus* and intermediate forms of *Homo* that appear more like *H. sapiens* but have not yet reached complete anatomic modernity. We refer to these groups as transitional *Homo* and pre-modern *Homo*, respectively, and discuss the significance, morphology, and key fossils of the taxa within these groups below.

Historical Background

Transitional *Homo: Homo habilis*

Significance

From 1960 to 1963, a series of fragmentary fossils were found in Olduvai Gorge, Tanzania, that seemed to belong to a new *Homo* taxon. Despite some morphological similarity to younger *Homo* remains, these fragments (OH 4, a mandibular fragment, and OH 6, cranial fragments and an

upper molar) were considered too incomplete to determine a new species. Instead, the announcement was made after the discovery of OH 7, an associated find of fragmentary parietal bones, a badly damaged juvenile mandible but with the tooth crowns in good condition, an isolated upper molar, and hand bones. The discoverers of OH 7 noted derived traits shared between this specimen and members of the genus *Homo*, but the endocranial volume of OH 7 was unusually small for *Homo*. The discoverers of OH 7 combined its announcement with a revision to the criteria for membership in *Homo* that reduced the requisite endocranial volume to only 600 cc and thus within the upper range of *Australopithecus*. This decision was met with objection by other researchers.

Since OH 7 was found in the same stratigraphic level as primitive (i.e., Oldowan) stone tools, it was dubbed *Homo habilis*, the Handy Man. In addition to proposing a new species of *Homo*, the announcement of *H. habilis* changed our understanding of the depth of the evolutionary history of the genus *Homo*. The stratigraphic level of OH 7 dates to 1.8 mya, a million years earlier than the previously known emergence date of *Homo*.

Morphology

Some researchers argue that *H. habilis* marks the first evidence for derived features such as encephalization (Tobias 1966: 1971), a more modern human-like cranium and face (Bromage 1989), and reduction in the size of the tooth and jaw size (Vandebroek 1969).

H. habilis appears especially distinct from *Australopithecus* in the shape of its cranial base (Wood 1996).

Until the discovery of potential tools at Dikika dating to 3.39 mya, *H. habilis* was also considered the oldest tool-making hominin. *H. habilis* has some modern human-like features of its hand bones that suggest the ability to craft tools. The trapezium, the wrist bone that articulates with the thumb, has a broad articular surface that would have allowed for a wide range of medial rotation, and *H. habilis* has broad apical tufts on the distal phalanges that suggest robust finger tips (Napier 1962; Tocheri et al. 2008).

However, some researchers consider the morphology of *H. habilis* too primitive for inclusion in the genus *Homo*. With an average of 680 cc among specimens, the cranium of *H. habilis* is only slightly larger than *Australopithecus*, and the crown areas of the cheek teeth are not notably reduced. Even the bones of the hand appear less modern human-like than originally believed. The phalanges are curved and robust, with fibrotendinous marks suggesting frequent climbing. Some aspects of the wrist, including broad lunate and scaphoid articular surfaces, also appear primitive. Whether or not *H. habilis* possessed the precision grip that defines modern human hands cannot be reliably determined from the current evidence.

Whether or not emerging *Homo* possessed the striding gait of modern humans is also a matter of debate. Although the foot of *H. habilis* (OH 8) possesses some adaptations for supporting the body during bipedal walking, its morphology does not suggest a propulsive role for the big toe. The foot overall retains apelike morphology consistent with climbing, and the femur has a knee joint not well adapted for modern bipedalism. It is possible that *H. habilis* shared a form of bipedalism with *Australopithecus* that was unlike the gait of *H. erectus* and later *H. sapiens*. Recently, some researchers have reopened the proposal that the OH 8 ft. may not belong to early *Homo* but to *Paranthropus boisei* (Gebo and Schwartz 2006).

Notable Fossils

In addition to the type specimen OH 7, Olduvai has yielded many fragmentary remains of *H. habilis*. Notable specimens include OH 8, dating to 1.76 mya. The fossils comprising OH 8 are a well-preserved left foot (see above), some dental fragments, and the adult hand bones originally grouped with OH 7. The foot is likely adult and therefore not part of the juvenile OH 7. However, some researchers argue that the foot is juvenile, in which case it could belong to the same individual as OH 7, and the remains of a tibia and fibula (OH 35) may also belong to the same individual (Susman and Stern 1982). However, this unlikely as the discrepancies in joint surfaces and the respective stratigraphic and spatial locations of

Fossil Records of Early African *Homo*,
Fig. 1 Fossil localities of transitional and premodern Homo in East and South Africa. Triangles denote discoveries of *Homo habilis* remains, *squares* denote discoveries of *Homo rudolfensis* remains, and *circles* denote discoveries of *Homo ergaster* remains. *Question marks* indicate that the affinities of specimens to specific taxa are uncertain. Note that most of the African continent remains unexplored

OH 7, OH 8, and OH 35 are not consistent with them belonging to the same individual.

Other discoveries of *H. habilis* at Olduvai include two fragmentary juvenile skulls (OH 13 and OH 16), a fragmented and distorted cranium (OH 24), and a partial skeleton (OH 62). The skulls of OH 13 and OH 16 date to 1.7 mya, and the OH 24 and OH 62 date to at least 100,000 years earlier. The OH 24 cranium includes derived cranial traits distinct from *Australopithecus* such as reduced postorbital constriction, an inverted V shape formed by the lambdoidal suture, and a more modern human-like mandible. The cranial capacity, however, is small even compared to the juvenile OH 7.

The OH 62 partial skeleton allows for a poor estimate of body proportions in *H. habilis*, and the forelimb to hindlimb proportions are suggested to be more apelike than those of *Australopithecus*. Although these differences in limb proportions may be the result of intraspecific variation, they may also be evidence that *H. habilis* did not share the locomotor style of later hominins.

Beginning in the 1970s, transitional *Homo* remains were also recovered from the site of Koobi Fora, Kenya (Fig. 1). KNM-ER 1813 is a nearly complete cranium with a cranial capacity of only 510 cc. It dates to 1.88–1.90 mya, although earlier dates have been proposed (Gathogo and Brown 2006). The incomplete skull KNM-ER 1805, which is possibly older than 1.87 mya, is similar to KNM-ER 1813, and both specimens are often designated as examples of *H. habilis*. However, some researchers argue that some unusual features of the cranium and teeth of KNM-ER 1805 preclude it from belonging to early *Homo*. A recent discovery at Koobi Fora, the KNM-ER 42703 maxilla, dates to 1.44 mya and expands the temporal range of *H. habilis* to much later than previously thought.

Also found at Koobi Fora is KNM-ER 3735, a partial skeleton with evidence of the cranium, the upper limb and its girdle, the sacrum, and the lower limb dating to 1.88–1.9 mya. The postcranial evidence of KNM-ER 3735 is more similar to *Australopithecus* than OH 62; the scapula and radius are especially apelike.

The geographic range of *H. habilis* expands beyond the boundaries of the principal sites of Olduvai and Koobi Fora. A fragmentary cranium,

L 894–1, dating to 1.8 mya, that comes from the Shungura Formation, Omo, Ethiopia, is comparable to OH 13 and OH 24. A maxilla from Hadar, Ethiopia (AL 666–1), extends the earliest known date of appearance for *H. habilis* to 2.3 mya. A temporal bone KNM-BC 1 from the Tugen Hills, Kenya, dates to 2.4 mya and has also been referred to transitional *Homo*.

One African specimen outside of eastern Africa has been likened to *H. habilis* though never formally included in its hypodigm. STW 53 is a well-preserved cranium from Sterkfontein, South Africa, that dates to at least 2.0–1.5 mya. Examination of the bony labyrinth of STW 53 suggests that it is not similar to later *Homo* and may have relied on less bipedal locomotion than *Australopithecus* (Spoor et al. 1994). Cladistics analyses that treat this specimen as its own taxonomic unit suggest it is a sister-taxon to a *H. habilis*/*H. erectus*/*H. sapiens* clade (Smith and Grine 2008).

Transitional *Homo* – *Homo rudolfensis*

Significance

Several of the transitional *Homo* fossils found at Koobi Fora, Kenya, in the 1970s were referred to transitional *Homo* and later subsumed within the *H. habilis* hypodigm (i.e., KNM-ER 1813). Others, however, exhibited more robust features than the Olduvai sample of transitional *Homo* (i.e., KNM-ER 1470). Aleexev (1986) argued that KNM-ER 1470, a cranium dating to 1.88–1.95 mya, was distinct enough to constitute a new species and recommended the name *Pithecanthropus rudolfensis*. Groves (1989) later transferred this taxon to *Homo* since the genus name *Pithecanthropus* was no longer used.

There remains considerable debate over the Koobi Fora sample of *H. rudolfensis* and whether it represents a taxon distinct from *H. habilis*. Some authors argue that the variation within a combined *H. habilis*/*H. rudolfensis* sample reflects a high degree of sexual dimorphism or anagenetic change rather than evidence of speciation. However, if the specimens belonging to *H. rudolfensis* are incorporated in the *H. habilis* hypodigm, the resulting interspecific variation is greater than seen in several extant ape species and the pattern of variation is different from that seen in any great ape or in modern humans. Additionally, KNM-ER 1813 shares with *H. habilis* buccolingually narrow premolars and molars, while KNM-ER 1470 does not. It is likely that two transitional *Homo* taxa are sampled at Koobi Fora.

Morphology

The suite of derived and primitive traits in the crania of *H. habilis* and *H. rudolfensis* are distinct. *H. rudolfensis* retains several primitive traits, including a thin-walled cranium with marked postorbital constriction and an inflated mastoid region, deep zygomatics, and larger postcanine teeth with more complex premolar and molar crowns and roots. The face of *H. rudolfensis* is also wider at the midface rather than the upper face as in *H. habilis* (Fig. 2). However, *H. rudolfensis* also has more some features more derived than *H. habilis*, including a more orthognathic face. At 800 cc, its endocranial volume is larger than *H. habilis* and larger than its contemporary KNM-ER 1813, which has a cranial capacity of only 510 cc. However, when the effects of body size are taken in account, the endocranial volume of KNM-ER 1470 and *H. habilis* is not significantly different.

Notable Fossils

There are several craniodental discoveries at Koobi Fora referred to *H. rudolfensis* but none as complete as the lectotype, KNM-ER 1470. There are no postcranial remains unequivocally referred to *H. rudolfensis*; the site at which potential *H. rudolfensis* postcrania have been found is also where cranial evidence of *P. boisei*, *H. habilis*, and *H. ergaster* has been found. Two femora, KNM-ER 1472 and KNM-ER 1481, *may* belong to *H. rudolfensis*.

A mandible found in 2.5–2.3 mya sediments of Uraha, Malawi (HCRP-UR 501), has also been referred to *H. rudolfensis*. If this designation holds true, it greatly expands the geographic and temporal range of this taxon.

Premodern *Homo*: *Homo ergaster*/*Homo erectus*

Significance

In the early 1890s, a hominin fossil found on the island of Java was classified as a new hominin

Fossil Records of Early African *Homo*, Fig. 2 Cranial comparisons of (*left to right*) *Homo habilis*, *Homo rudolfensis*, *Homo ergaster*, and *Homo sapiens* in portrait (*top row*) and profile (*bottom row*) views. Casts represent Koobi Fora specimens in the collection of the National Museums of Kenya and a modern human

called originally *Anthropopithecus erectus* and later *Pithecanthropus erectus*. This discovery, the Trinil calotte, demonstrated a smaller brain size and more primitive features than the two species of *Homo* (*H. sapiens* and *H. neanderthalensis*) known at the time of its discovery. The calotte was also much older than these taxa, dated originally to 500,000 years old and later closer to between 700,000 and 1 mya. Similar finds were subsequently discovered at the site of Sangiran, also on Java and at what is now called Zhoukoudian, in China. The overall similarity of the cranial morphology of these Asian specimens to modern *Homo* eventually led to their inclusion within the genus as *Homo erectus*.

Fossils of similar morphology were later found in Koobi Fora and dated to around 1.5 mya, 0.5 mya older than the Trinil calotte. Although the Koobi Fora specimens shared some of the derived features of *H. erectus*, they were less well defined. For example, *H. ergaster* generally had thinner cranial vaults, less sagittal keeling, and larger and more complex premolars. Groves and Mazak (1975) argued that these early African specimens do not share the morphology of Asian *H. erectus* and they provided a new species name, *Homo ergaster*, for the East African sample. However, some researchers argue that the East African sample is an early form of *H. erectus* that does not require a separate name and they refer to this taxon as "early African *Homo erectus*" (Kramer 1993).

Morphology

Homo ergaster is, in general, more modern-human like than transitional *Homo*. The mandible of *H. ergaster* is reduced in size compared to transitional *Homo* as is the dentition of *H. ergaster*. However, the endocranial volume of *H. ergaster* is still relatively small, and when body size is taken into account, the endocranial volume is not significantly larger than *Australopithecus*.

Homo ergaster is the earliest hominin to demonstrate a modern body form. *H. ergaster* is also larger than hominins of the past, with an especially significant increase in the height of females. The lower limbs of *H. ergaster* and its modern thoracic shape suggest bipedal locomotion, with no evidence of climbing adaptations. Cross-sectional measures of the femoral and humeral shafts demonstrate a modern human-like strength in the forelimbs and hindlimbs, and the pelvis is similar to modern humans. Additionally, the semicircular canal structure of the inner ear is similar to modern humans and suggests upright posture (Spoor et al. 1994). It is probable that *H. ergaster* was capable of long-distance walking and transport and possibly adapted to endurance

running. Archaeological evidence from *H. ergaster* localities suggests that raw materials for stone tools were being carried over long distances (Anton 2003).

Notable Fossils

The KNM-ER 992 mandible that dates to 1.5 mya is the type specimen of *H. ergaster*. The first well-preserved cranium of *H. ergaster* to be recovered is KNM-ER 3733, which dates to 1.78–1.65 mya; it has an endocranial volume of about 848 cc. This is similar to the endocranial volume estimates for KNM-ER 3883, an *H. ergaster* calvaria that dates to 100,000 years later. The 1.55 mya cranium without a face, KNM-ER 42700, is referred to *H. ergaster*, but it has an estimated adult body size more similar to transitional *Homo*. This relatively large range of body size suggests that *H. ergaster* may have retained a high degree of sexual dimorphism.

Among the postcranial remains known for *H. ergaster*, two notable discoveries are KNM-ER 803, a partial skeleton dating to 1.5 mya, and KNM-ER 3228, a 1.9-million-year-old pelvic bone. These fossils provide evidence that *H. ergaster* shared a similar walking pattern with modern humans.

Perhaps the most significant fossil remains of *H. ergaster* are those of KNM-WT 15000 (Turkana Boy), a well-preserved skeleton of an 8–12-year-old boy dating to 1.55 mya. Found in 1984, KNM-WT 15000 took four seasons to excavate and is one of the most complete skeletons in the early human fossil record. The discovery demonstrates conclusively that *H. ergaster* possessed modern limb proportions and a modern body shape. The teeth of KNM-WT 15000 provide for some life history reconstruction, and it has been determined that *H. ergaster* shares a similar dental development pattern with transitional *Homo* (Dean and Smith 2009). This suggests that modern life history patterns originated late in human evolution. Turkana Boy also has a cranial capacity of 909 cc, which is still small relative to later *Homo*.

All specimens formally referred to *H. ergaster* come from Kenya, but other *H. ergaster*-/*H. erectus*-like remains have been found in Ethiopia, Tanzania, and South Africa. At Konso, Ethiopia, the left side of mandibular corpus with preserved postcanines was found in association with Acheulean tools. This specimen, KGA 10–1, dates to 1.4 mya and has strong similarities to KNM-ER 992.

At Olduvai, several specimens have been formally referred to early African *H. erectus*. The OH 9 partial calvaria has a well-preserved supraorbital region and dates to 1.5–1.2 mya. The OH 12 skull, which comprises a fragmentary calvaria plus part of the mandible, is more recent (c. 0.78 mya) yet its endocranial volume of 727 cc is substantially smaller than that of OH 9.

Among the hominin remains at Swartkrans, SK 15, SK 45, and SK 847 have been referred to early *H. erectus*. SK 15 is a distorted mandibular corpus dating to 1.5–1.0 mya, and SK 45 is a fragment of the right mandible dating to 2.0–1.5 mya. SK 847 is known as the "Composite Cranium" and also dates to 2.0–1.5 mya. In 1969, 20 years after their discovery, Ron Clarke realized that the fossils SK 80, SK 846, and SK 847 belonged to the same individual. Today, SK 847 is composed of the left side of the face and cranial base. Some authors argue its affiliation is with *H. erectus*, but others refer all three of these specimens to transitional *Homo* (Strait et al. 1997).

Key Issues/Current Debates

Phylogenetic Relationships

Phylogenetic analyses demonstrate that *H. habilis* is not consistently grouped more frequently with *Homo* than with *Australopithecus*, and some argue for its removal from the hypodigm of *Homo*. Still other researchers maintain that there exists phylogenetic support for a clade of *Homo* that includes *H. habilis*, with *H. habilis* as the possible sister-taxon of *H. ergaster*. Regardless of whether or not *H. habilis* belongs in the genus *Homo*, it is unlikely to prove an ancestor of later hominins such as *H. ergaster* because some remains of *H. ergaster* are found in the same fossil localities and date to the same era as *H. habilis*.

Homo habilis and *H. rudolfensis* overlap significantly both temporally and geographically,

and their potential sister-taxa relationship is often debated. Like *H. habilis*, *H. rudolfensis* does not group consistently with *Homo*, and it is possible this taxon represents a member of *Australopithecus*. However, *Homo rudolfensis* may also represent a better candidate for the ancestor of *H. ergaster*/*H. erectus* than *H. habilis* based on its cranial shape (Gonzalez-Jose et al. 2008). This ancestral relationship, however, is unlikely since *H. rudolfensis* and *H. ergaster* also overlap considerably in time and place (Fig. 3).

H. ergaster's inclusion in the genus *Homo* is well established, but its relationships to other *Homo* taxa are debatable (Fig. 4). *Homo ergaster* overlapped significantly in time and place with members of transitional *Homo*, suggesting they do not have an ancestor-descendant relationship. Similarly, the earliest known emergence dates of *H. ergaster* in Africa and *H. erectus* in Asia are close, and it is hard to reconstruct an ancestor-descendant relationship between these two taxa if these earliest known dates of emergence are correct. Although traditionally described as "early African *Homo erectus*," *H. ergaster* may be a sister-taxon of *H. erectus* or both taxa may be descendants of an earlier taxon.

Dispersal from Africa

Paleoenvironment

Transitional *Homo* and *H. ergaster* are known from 1.9 mya and older geological sediments in East and Southern Africa. Around 2 mya, Africa experienced great climate change, especially increasing aridity. Olduvai fossil plants from the same stratigraphic level as OH 7 imply the emergence of more grasslands during this time, and high C_4 isotopic signals suggest the same (Cerling 1991). High C_4 signals have also been found in the lacustrine sediments around Koobi Fora (Cerling et al. 1988) and in Southern Africa (Hopley et al. 2007). Grazing bovids appear to become more prevalent in East Africa around 2.4 mya, also suggesting the emergence of more grassland. Current environmental reconstructions suggest that transitional *Homo* and *H. ergaster* evolved during a time of increasing complexity and heterogeneity in the landscape, which was likely composed of a mixture of closed forests and open grasslands. While the fossil and archaeological records of transitional *Homo* do not yet support long-distance travel, it is reasonably certain that *H. ergaster* made use of a wider range of landscapes than previous hominins. Certainly the presence of *H. erectus* in East Asia implies that hominins must have left Africa sometime before 1.3 mya ago.

Out-of-Africa and the Multiregional Hypothesis

Historically, there are two theories concerning the dispersal of hominins beyond Africa. The "Out-of-Africa" Hypothesis argues that the genetic changes giving rise to modern humans evolved only once in an African population and then dispersed to Asia and Europe and subsequently the rest of the world. This theory has since been divided into Out of Africa I (the dispersal of *H. ergaster*/*H. erectus*) and Out of Africa II (the dispersal of *H. sapiens*). Genetic evidence demonstrates that the most parsimonious origin for modern DNA variation is Africa, lending support for this theory. The alternative hypothesis, the "Multiregional Hypothesis," argues that gene flow between hominin populations gave rise to modern humans. Neanderthal DNA is more similar to non-African populations of modern *Homo*, suggesting some interbreeding between *Homo* populations. The debate between Out-of-Africa and the Multiregional Hypothesis is ongoing; new morphological and molecular data promise to provide some resolution in the coming years (Fig. 5).

Early Fossil Evidence of Homo *Outside of Africa*

While this review has focused on the fossil records of transitional *Homo* and *H. ergaster*/*H. erectus*, there are several sites outside of Africa that show evidence of these hominins or very similar taxa. Morphological analyses of these fossils provide an especially rich source of information for assessing the migration patterns of premodern hominins and the evolutionary origin of *H. sapiens*. These fossils deserve their own review, and we include here only a few highlights found in the Republic of Georgia and China.

Fossil Records of Early African *Homo*, Fig. 3 Specimens mentioned in this review plotted against their age (averaged). *Triangles* denote discoveries of *Homo habilis* remains, *squares* denote discoveries of *Homo rudolfensis* remains, and *circles* denote discoveries of *Homo ergaster* remains. *Stars* denote comparative Asian specimens of both transitional and premodern *Homo*. Note the high degree of overlap between transitional and premodern *Homo* specimens, suggesting that *Homo ergaster* does not represent a descendant of the transitional *Homo* taxa known to date

At the site of Dmanisi in the Republic of Georgia, a *Homo* mandible dating from 1.85 to 1.78 mya has been referred to the *H. ergaster*/*H. erectus* hypodigm. This mandible shares with *Homo* its small size, relative gracility, and symphyseal shape, but the mandible is also smaller than the earliest *Homo* currently known and includes a diminutive P_4, M_2, and M_3. The premolars are especially narrow, similar to OH 13, a representative of *H. habilis*. The discovery of several skulls at Dmanisi sharing a unique combination of transitional *Homo* and premodern *Homo* traits has led some researchers to propose a new taxon, *Homo georgicus*, for this population, and at least one phylogenetic analysis suggests the cranial shape is similar to *H. ergaster* samples (Rosas and Bermudez De Castro 1998). The postcrania of the Dmanisi fossils are a mosaic of primitive and derived traits, combining a small estimated body size and an encephalization coefficient within the range of *H. habilis*. There is no evidence of the humeral torsion seen in later *Homo*, and the glenoid cavity is cranially oriented as in apes, suggesting the retention of adaptations for climbing. The clavicle, however, is modern like *H. ergaster*/*H. erectus*. The Dmanisi hominins also appear to have modern body proportions, including relatively long lower limbs.

Fossil Records of Early African *Homo*, Fig. 4 Four hypotheses of the taxonomic and phylogenetic relationships of transitional and premodern *Homo* remains (there may be others). (**a**) A conservative hypothesis that places specimens referred to *Homo rudolfensis* within *Homo habilis* and specimens referred to *Homo ergaster* within *Homo erectus*. This phylogeny also indicates a direct descendant relationship between transitional *Homo*, premodern *Homo*, and modern humans. (**b**) A sister-taxa hypothesis that suggests an unspecified transitional *Homo* ancestor (possibly *Homo habilis* or *Homo rudolfensis*) gives rise to the sister-taxa *Homo ergaster* and *Homo erectus*. Modern humans are descendants of *Homo erectus*. (**c**) An anagenetic hypothesis suggesting that *Homo ergaster* is an early form of *Homo erectus*, descended from *Homo habilis*, and gives rise to modern humans. This phylogeny also shows *Homo habilis* and *Homo rudolfensis* as sister-taxa. (**d**) A second anagenetic hypothesis, in which *Homo ergaster* is instead descended from *Homo rudolfensis*

Longgupo Cave, a 1.96–1.78-million-year-old site in the Sichuan Province of China, is the site of another mosaic hominin referred to both *H. ergaster* and *H. habilis*. The Longgupo Cave remains include a fragmentary left mandible and right upper later incisor, originally referred to *H. erectus*. The same authors, however, note affinities with *H. habilis* and *H. ergaster*. The mandibular corpus of Longgupo Cave hominin is small for this taxon and the cusp morphology more primitive, leading some authors to identify it as an ancient ape (Etler et al. 2001). The P_4 is especially distinct from the hypodigm of Asian *H. erectus*, having different talonid and root morphologies. Like other transitional *Homo* remains, the Longgupo Cave hominin was found in

Fossil Records of Early African *Homo*,
Fig. 5 Possible scenarios of the origin of modern humans from early *Homo*. (**a**) The Out-of-Africa Hypothesis, in which modern humans evolve from an *Homo ergaster*/ *Homo erectus* population in Africa, disperse throughout the world, and replace existing archaic hominin populations. (**b**) The Multiregional Hypothesis, in which early *Homo* populations regularly encounter and interbreed with each other, eventually giving rise to regional but regularly interbreeding populations of modern humans

association with two items that may represent Oldowan tools.

A second fossil site from China dating to the same era as Longgupo Cave is Yuanmou Cave in southwest China. The incisors of a hominin found in this cave strongly resemble the incisors of *H. ergaster* and have similarities to *H. habilis*. The Yuanmou Cave hominin was also found in association with stone tools.

Future Directions

We are the last surviving species of a diverse hominin lineage. Previous members of our genus, *Homo*, were likely the earliest hominins to spread beyond Africa, having expanded beyond that continent by at least 1.8 mya. The diversity of transitional and premodern *Homo* forms is a testimony to the adaptive radiation of hominins to

occupy new landscapes and ecological niches in a changing world 2 million years ago. The evolutionary and cognitive abilities that have enabled modern humans to occupy many different environments have their origins millions of years prior to the emergence of *H. sapiens*. Ongoing analysis of our fossil relatives *H. habilis*, *H. rudolfensis*, and *H. ergaster* will improve our understanding of these abilities and help us reconstruct the phylogenetic history of our lineage. Like the many modern human populations we observe today, these fossils of early *Homo* provide us with a view of the great antiquity of human migration, adaptation, and diversity.

Fossil Records of Early Modern Humans

Ian Tattersall
Division of Anthropology, American Museum of Natural History, New York, NY, USA

Introduction

Efforts to understand the origin of *Homo sapiens* were bedeviled for decades by the inclusion within our species of a host of late Middle or Late Pleistocene "archaic" fossils possessing cranial morphologies that deviated, sometimes enormously, from those we see among humans living today. In recent years, however, it has begun to dawn on some paleoanthropologists that modern *Homo sapiens* is actually very distinctive, and highly derived in its morphology, and that it

makes most biological sense to include within this species only fossils that bear significant osteodental hallmarks of the living form (Tattersall and Schwartz 2009; Schwartz and Tattersall 2010). This morphological requirement makes the search for the origins of *Homo sapiens* more straightforward, although not necessarily easier.

Definition

Without doubt, the single most significant cranial apomorphy of the living species *Homo sapiens* is the retraction of its small facial skeleton beneath the front of a more or less globular braincase (that averages some 1,330 ml in volume: Holloway et al. 2004). This complex and ramifying feature is most exhaustively documented and discussed by Lieberman et al. (2002; see also Lieberman 2011), who plausibly suggest that facial retraction is associated both with the extreme flexion of the *Homo sapiens* cranial base and with the typical rounding of the well-inflated human cranial vault in side view. It is this overall ensemble that gives the modern human skull its very characteristic Gestalt; but several more detailed features (some of them possibly also developmentally correlated) additionally appear to be *Homo sapiens* autapomorphies.

Such detail autapomorphies include extension of a deep and compressed vaginal process to the margin of the ectotympanic tube; approximation of the vaginal process to the mastoid process; extreme lateral placement of the styloid process, with the stylomastoid foramen lying very posteromedially at its base; narrow, high, occipital plane of the occipital bone; retention into the adult of a discernible arcuate eminence on the superior internal face of the petrosal; fully segmented cranial sutures, with some segments deeply interdigitated; bipartite brow area, in which a medial segment continuous with a more or less swollen glabella is undercut by a distinct lateral plate that originates around the supraorbital notch; mandibular symphysis that is thicker than the corpora behind it when seen from below; and a chin in the form of an "inverted T," with a vertical central keel bounded by depressions on either side, and a horizontal bar below running between more or less well-defined lateral tubercles (Schwartz and Tattersall 2005). Additional *Homo sapiens* characters that have also been noted include an unenclosed subarcuate fossa and an inferior orbital plane that tilts down and back from the inferior orbital margin (Arsuaga et al. 1997).

Together, these characteristics produce a cranium of highly individual aspect, and the postcranial skeleton is equally distinctive. A recent composite reconstruction of a Neanderthal skeleton by Sawyer and Maley (2005) appears to be reasonably representative of the structure of robust Middle Pleistocene *Homo* in general (Tattersall 2010), and comparing it with its counterpart in *Homo sapiens* emphasizes just how autapomorphic the latter species is in its postcranial morphology as well as its skull structure. This highly derived condition is dramatically visible in the overall gracility of the *Homo sapiens* postcranial skeleton, and it is most specifically observed in the barrel-shaped rib cage that tapers in at the top and the bottom and in the matching narrowness of the pelvis, with its laterally compressed iliac blades and short pubic rami. All in all, despite some variation in its defining cranial and postcranial features, today's *Homo sapiens* is a highly distinctive morphological entity. But when we broaden the scope to the fossil record, some grayer areas emerge.

Key Issues/Current Debates

The Fossil Record: Africa

Leaving aside the motley assortment of hominins in the 500–200 ka age range that have been called "archaic *Homo sapiens*" despite possessing morphologies very unlike those of modern humans, the earliest generally accepted *Homo sapiens* fossils are known exclusively from African sites younger than 200 ka. Best preserved among these is one of three crania from the Ethiopian Middle Awash site of Herto that are dated to between 160 and 154 ka (White et al. 2003). With a braincase volume of some 1,450 ml, the

BOU-VP-16/1 cranium (along with the other Herto specimens) was referred by its describers to a new subspecies of *Homo sapiens*, *H. s. idaltu*, because it is "morphologically just beyond the range of variation" seen in the living species (White et al. 2003). Its allocation to *Homo sapiens*, at least, seems provisionally reasonable based on rather scanty published information. Whether the recognition of a distinct subspecies is wise, or even useful, is a separate and perhaps trivial question.

Unfortunately, it is unclear whether the two most striking skull details of the living species, the bipartite brow and the chin, are present in the Herto skull: the brow region is damaged and its detail undescribed, while the mandible is unknown. But interestingly, these two features are indeed absent in the oldest credible candidate of all for "anatomically modern *Homo sapiens*." This is Omo Kibish 1, a fragmentary skull from southern Ethiopia that has been dated to as much as 195 ka (McDougall et al. 2005). As reconstructed by Day and Stringer (1982), Omo 1 has a tall, roomy cranium with a *Homo sapiens*-like high occipital plane. Atypically for our species, however, the occipital is undercut by a transverse sulcus; and while in the mandible there is a low swelling in the symphyseal midline, there is no classic "chin," with vertical keel and horizontal bar. What is more, the incomplete supraorbital margins are pinched inferosuperiorly, and it seems very unlikely that they were originally bipartite. A second and penecontemporaneous cranium from Omo Kibish has a more complete braincase of 1,435 ml volume, but its proportions are not those of the extant form, and despite their common provenance, it is hard to see the two fossils as members of the same population.

Interestingly, there is a suite of later fossil hominins from southern Africa that also show the Omo 1 pattern of basically *Homo sapiens* skull morphology in the absence of the modern chin and/or bipartite brow (Schwartz and Tattersall 2005). These include specimens (from Border Cave [BC5], Boskop, Fish Hoek, and most from Klasies River Mouth), that span a period of almost 100 kyr (some of the KRM fragments appear to be well over 100 kyr old, while the Fish Hoek cranium has been dated to around 12 ka: Singer and Wymer 1982; Deacon and Wilson 1992). Given that an admittedly rather spotty record in the region also includes individuals of more comprehensively modern morphology (e.g., Border Cave 1 and 2, KRM AP 6222, Hofmeyr) throughout much of this period, it seems legitimate to conclude that aspects of an Omo 1/Herto-like morphology may have been primitive for *Homo sapiens* or at least common as variants among its early populations. Subsequently, such conformations became lost in African populations, their last traces disappearing only quite recently.

At the very least, the Omo and Herto fossils are in the right places, at the right times, to have been very early members of our species: molecular comparisons among modern populations indicate strongly that *Homo sapiens* originated somewhere in sub-Saharan Africa, and coalescence calculations converge on a date of origin for our species in the period following about 200 ka (Harpending and Rogers 2000; Campbell and Tishkoff 2010; Scheinfeldt et al. 2010).

Perhaps a bit unusually for such an osteologically distinctive form, the larger phylogenetic context in which the species *Homo sapiens* appeared remains quite opaque. Unlike *Homo neanderthalensis*, for example, which has well-established antecedents in the fossil record (most notably at the Sima de los Huesos at Atapuerca), *Homo sapiens* lacks clear fossil precursors. Apart from the specimens just discussed, which may provisionally be subsumed into the living species, there are no almost-but-not-quite *Homo sapiens* fossils known in the African record: nothing, for example, that possesses the facial retraction of the modern form in the absence of other *Homo sapiens* autapomorphies (or vice versa). African representatives of *Homo heidelbergensis* such as Kabwe, Bodo, and Saldanha most emphatically do not fill this particular morphological role, even though *Homo heidelbergensis* is often considered a strong candidate for ancestor of *Homo sapiens*. Such more recent specimens as the apparently pathological >133 ka Singa cranium from Sudan (McDermott et al. 1996), the fragmentary

>180 ka Guomde skull from East Turkana in Kenya (Brauer et al. 1997), and the badly damaged >200 ka Eliye Springs specimen from the western side of the same basin (Brauer et al. 2003) remain problematic, while fossils such as those from Ngaloba, Ndutu, and even Florisbad that have at one time or another been described as "archaic *Homo sapiens*" do not obviously group monophyletically with our species (Schwartz and Tattersall 2005, 2010).

If the hominin fossil record as it stands has any reliability whatsoever as an indicator of actual phylogenetic history, it is thus looking increasingly probable that the anatomically distinctive species *Homo sapiens* was born in a single event of altered gene regulation or expression, presumably minor at the genomic level, that had cascading developmental effects throughout the body.

Perhaps the nearest thing we have to a "close but [probably] no cigar" situation is found among hominin fossils from northern Africa that have broadly Aterian or pre-Aterian associations. The ~160 ka crania from Jebel Irhoud in Morocco have often been loosely considered *Homo sapiens*, and a juvenile jaw from the site exhibits a dental developmental schedule comparable to our own (Smith et al. 2007). But the best-preserved Jebel Irhoud adult skull (JI 1) has a rather squat braincase of 1,305 ml volume, in addition to a substantially unretracted face that, while smallish, is distinctive in structure from its counterpart in *Homo sapiens* (Schwartz and Tattersall 2005). The Jebel Irhoud hominids resemble in some respects the marginally more *Homo sapiens*-like ~80 ka (Barton et al. 2009) cranium from Dar es-Soltan, also in Morocco, and perhaps additionally a very badly crushed and fractured ~108 ka adolescent cranium from a third Moroccan site, Contrebandiers Cave (Balter 2011). Together, all of these specimens may turn out to constitute a morphologically (and perhaps also culturally) distinctive regional morph, one that might have shared a fairly recent common ancestry with more fully recognizable *Homo sapiens*. And indeed, if anatomically distinctive *Homo sapiens* originated from a less derived ancestor in a single major reorganizational event, then we might not expect ever to find anything anatomically much closer to it.

The Fossil Record: The Near East

Perhaps not unexpectedly, the earliest fossil occurrence of clearly anatomically modern *Homo sapiens* outside Africa occurs in the Levant, a region often considered to be a biogeographic extension of the continent to its south, and situated athwart the major exit route from it. The fossils in question are from the cave site of Jebel Qafzeh, in Israel, and are dated to around 95 ka (Bar-Yosef 1998). Associated with Mousterian lithics, hominid remains from this site have all been allocated to *Homo sapiens* (Vandermeersch 1981). But while two of the individuals concerned (the subnasally prognathic adult Q9, of 1,531 ml cranial volume, and the immature Q11) are clearly of entirely modern *Homo sapiens* morphology (as are Q1 and 2 which are intrusive more recent burials), the majority of the Qafzeh fossils are anatomically non-modern. The best-preserved cranium among these latter is Q6, which has protruding supraorbital margins that are continuous across glabella, together with a smallish but poorly retracted face. It also lacks many of the detailed *Homo sapiens* apomorphies listed above (Schwartz and Tattersall 2005, 2010), although it has an impressive cranial volume of 1,568 ml (Holloway et al. 2004). Including all of the Qafzeh hominids in *Homo sapiens* certainly simplifies interpretation, but it clearly obscures the evident morphological complexity at this site.

What might explain the morphological heterogeneity at Qafzeh? There are only three potential scenarios possible, namely, that all the hominids are *Homo sapiens*; that two distinct kinds of hominid occur at the site, one of them represented by Q9 and the other by Q6; and that hybridization was occurring between two entities at Jebel Qafzeh, one of them evidently anatomically modern *Homo sapiens*. If the first possibility is the correct one, it would unsettlingly imply that our species is undefinable morphologically. In that case, all systematic bets would be off (by implication across the hominin board), and there would basically be no utility whatever in seeking the origin of our morphologically distinctive species in the fossil record. One rather hopes this is not the case.

If the second possibility in fact applies, we have recognizable *Homo sapiens* at Qafzeh, plus a second species that has not been named and may be unknown from elsewhere.

The third option is the most intriguing, especially in view of the curious morphology exhibited by the hominids from Skhūl, another site in Israel that are probably substantially older than 100 ka (Grün et al. 2005). The Skhūl fossils were originally described (together with the Tabūn Neanderthals) under the name of *Palaeanthropus palestiniensis* just before the outbreak of World War II (McCown and Keith 1939). This name actually appears to be a nomen nudum, since no holotype was specified for it, and it was applied equally to the Skhūl and Tabūn populations – which are now acknowledged to represent distinct hominin species. In any event, the new name never caught on, and for the last half-century or so, the Skhūl fossils have generally been crammed into *Homo sapiens*. It is not easy to understand why. With fairly nicely rounded braincases of 1,450–1,590 ml in volume (Holloway et al. 2004), the Skhūl hominins do have faces of modest size. But those faces are poorly retracted at best, and while there is some variation within the Skhūl sample in supraorbital conformation, all individuals agree in lacking the classic *Homo sapiens* morphology. What is more, in the best-preserved specimens (Skhūl II and Skhūl V), this region is very aggressively unlike *Homo sapiens* in being transversely bar-like and more or less continuous across glabella. Further, while there is some swelling at the lower anterior border of the symphysis in all of the adult Skhūl mandibles, none of them shows any hint of the complex human chin morphology. Interestingly, although the best-preserved specimens from Qafzeh and Skhūl (Q6 and Skhūl V) present distinctively different Gestalts, some resemblances between other individuals from the two sites have been recorded (Schwartz and Tattersall 2010).

Altogether, the fairly chaotic assortments of morphologies at Qafzeh and Skhūl invite the speculation that some hybridization among different hominid lineages may have occurred in the Levant. When such speculations have been made in the past, they have involved mingling between *Homo sapiens* and *Homo neanderthalensis*: a species that is well documented to have occurred in the region in the same general time frame. The morphological consequences of interspecies hybridization among hominids are at best poorly understood, but the radical morphological differences between Neanderthals and moderns, and the difficulty of detecting any specifically Neanderthal features in the Skhūl and Qafzeh hominids, do suggest that such intermingling was likely not the case. A more plausible scenario of intermixing might involve Levantine hybridization between emigrating North African Aterians (exiting the continent eastwards along the continent's northern coast, thence north through the Sinai peninsula), and *Homo sapiens* of ultimately Eastern African origin (migrating northwards along the Nile corridor). Intuitively, this seems to make better morphological sense; and in the time around 120–100 ka, the initial separation of the two populations would have been a relatively recent event. What is more, the levels of technological sophistication of these two groups (hence possibly their cultural compatibility) would have been comparable to each other—as, admittedly, they also evidently were to that of *Homo neanderthalensis*, a hominin species that was already resident in the Levant, at least episodically.

Whatever the exact case, and however the curious mixture of Levantine morphologies will eventually be explained, the early foray of anatomically (but not behaviorally) modern *Homo sapiens* out of Africa that is confirmed by the Qafzeh 9 and 11 fossils (and also by recent archaeological findings in Arabia: Armitage et al. 2011) appears to have been short-lived – as apparently were any putatively hybrid populations. Due either to climatic vicissitudes or to competition, or to a combination of both, *Homo sapiens* soon found itself confined once more to Africa. Molecular comparisons (of mtDNA, Y-chromosome DNA, and some nuclear autosomal markers) suggest that expanding populations (which were evidently both anatomically and behaviorally

modern) later reemerged from Africa at around 70–60 ka (see Maca-Meyer et al. 2001). This exodus likely followed a severe contraction of the already thinly spread *Homo sapiens* population during the climatic vicissitudes of MIS 4, and probably in the wake of (though most likely not as a direct result of) the super eruption of Mount Toba in Sumatra at about 74 ka.

The Fossil Record: Europe and Asia

Following the 70–60 ka exodus from Africa, *Homo sapiens* rapidly spread to the ends of the Eurasian continent. By ~40 ka, armed with an Aurignacian toolkit, it had begun flooding into western Europe (Mellars and French 2011), a region already occupied by Neanderthals. This early stage of colonization is documented by numerous archaeological sites but relatively few fossils, although the late Aurignacian (>31 ka) Mladeč crania from the Czech Republic are clearly anatomically modern (see Teschler-Nicola 2006). Following the end of the Aurignacian, the record rapidly picks up, with numerous standard-issue *Homo sapiens* fossils from classic Gravettian sites such as Cro-Magnon and the Abri Pataud.

At the very early end of the timescale, though, some paleoanthropologists (e.g., Rougier et al. 2007) have found it tempting to propose that such *Homo sapiens* fossils as the ~40 ka cranium and mandible from the Peştera cu Oase in Romania show various "archaic" features that are attributable to "complex population dynamics" (for which read: "hybridization with Neanderthals"). Similarly, a Gravettian child's skeleton from the Portuguese Abrigo do Lagar Velho has been reported to show Neanderthal-like features (Duarte et al. 1999), even though this individual lived at least 100 generations after the final disappearance of *Homo neanderthalensis* from Iberia.

In both of these cases the various morphologies concerned, while interesting, offer on closer examination no convincing indications of Neanderthal admixture (Schwartz and Tattersall 2010). Indeed, the fossil record makes it pretty clear that, although the recently announced draft Neanderthal genome (Green et al. 2010) is said to offer some evidence for a low level of (oddly one-way) genetic introgression (1–4%) from Neanderthal into modern populations at an early stage, any early introgression there may have been was evidently not biologically significant, i.e., it did not materially affect the subsequent morphological or evolutionary histories of either species.

In Australia, the earliest physical evidence for human occupation comes from two gracile early modern human burials at Lake Mungo in New South Wales. Dated to ~40 ka (Bowler et al. 2003), they occur some 10 kyr after the first evidence for human habitation both in the region and on the continent. Australia was then virgin territory for hominins, something that cannot be said for Java, where the *Homo erectus* lineage is documented as late as about ~40 ka (Swisher et al. 1996). By this time, we can fairly safely surmise that *Homo sapiens* had already arrived on the island, although the earliest recorded occurrence of modern humans in island southeast Asia, the cranium from Niah Cave in Borneo, is also dated to ~40 ka (Barker et al. 2007).

On the Asian mainland, *Homo erectus* may well have already been displaced by *Homo heidelbergensis* (known in China from Dali and Jinniushan), which was presumably the hominid in residence when *Homo sapiens* arrived. The earliest clear evidence for the advent of *Homo sapiens* in China is a partial skeleton, including a mandible with a distinct chin, from the cave site of Tianyuan, near Beijing (42–39 ka: Shang et al. 2007). It is just possible that a clearly *Homo sapiens* skull from Liujiang in southern China is considerably older than this, but the exact provenance of this specimen is greatly disputed (contrast Shen et al. 2002 with Wu 2004). A recently described "*Homo sapiens*" mandibular fragment from the Zhirendong Cave, also in southern China, seems more reliably dated to >100 ka (Wu et al. 2010), but despite the presence in this specimen of a low swelling at the anterior base of the symphysis, it is largely edentulous, lacks the hallmarks of the *Homo sapiens* chin, and is in general pretty undiagnostic. At present then, there is no really reliable evidence for the presence of modern *Homo sapiens* in China prior to about 40 kyr ago.

Future Directions

Modern *Homo sapiens* is a morphologically distinctive (and highly derived) species that originated in sub-Saharan Africa as indicated by both fossil and molecular evidence. The main elements of the characteristic modern morphology, notably the small face fully retracted below a tall, rounded cranium, are first seen in Ethiopian fossils dating to between about 195 and 160 kyr ago. However, two of the features of the modern form, namely, the bipartite brow area and the complex chin, were most likely absent in both of these individuals and apparently did not become universal among *Homo sapiens* in sub-Saharan Africa until the very end of the Pleistocene. The northern African Aterians (broadly defined) seem to represent a distinctive population that evolved independently in the Saharan region and its northern fringes at a time when the region was substantially better watered than at present. Aterian populations may have spread before 100 Ka to the Levant, where they intermingled with anatomically (but not behaviorally) modern humans who were following the Nile Corridor north at around the same time. This scenario would account for the odd combination of morphologies found at Levantine sites such as Qafzeh and Skhūl, and also for the contemporaneous occurrence of typical *Homo sapiens* individuals at the former.

In any event, the record strongly suggests that *Homo sapiens* first exited Africa at over 100 Ka but subsequently became reconfined to that continent, from which it emerged once more, equipped with a modern behavioral repertoire, at around 70–60 ka. By about 40 ka, fossil remains of fully modern *Homo sapiens* testify that the descendants of those second-wave émigrés had become established as far afield as in western Europe, Australia, and eastern China. In Australia (as, later, they did in the New World), they encountered virgin territory, but both in Europe and eastern Asia, modern humans would have encountered entrenched hominid populations. The exact nature of any putative interaction among the residents and the newcomers is barely documented, if at all, and must for the moment remain conjectural. However, the frustratingly slender relevant fossil record lacks any firm indication of significant genetic interchange among expanding *Homo sapiens* and the hominid residents whose territory they invaded – and whose disappearance followed close on their arrival.

Fourier Transform Infrared Spectroscopy (FTIR): Applications in Archaeology

Amy V. Margaris
Department of Anthropology, Oberlin College, Oberlin, OH, USA

Introduction

Few techniques for chemical analysis are as rapid and informative as Fourier transform infrared spectroscopy (FTIR). FTIR can be used to identify and compare sample compositions and in a quantitative fashion to determine the concentration of different components of a mixture (Smith 1999: 1). Its popularity in the field of conservation reflects attributes that make the technique appealing for many archaeological applications as well, including the small amount of sample required for analysis (milligrams or micrograms) and the fact that samples can be organic or inorganic and have a crystalline or amorphous structure. Its wide applicability makes FTIR a particular asset to nearly any professional archaeology laboratory as it can aid in determining the composition of such materials as fired clays, bone and tooth enamel, wood ash, fibers and dyes, plasters, and resins.

Infrared spectroscopy (IR) is used to identify the functional groups that are the building blocks of molecules. Examples include the amides found in silk proteins and the phosphate component of bone mineral. In brief, a sample is exposed to a beam of infrared radiation and responds by vibrating (bending and stretching) in patterns unique to each functional group. Older IR devices worked by separating out individual infrared frequencies and recording the interaction of the sample with each. FTIR trumps these by using a special optical device called an interferometer to measure the interaction of a sample with all infrared frequencies simultaneously. An automated mathematical procedure (the Fourier transform) translates the resulting interferogram into a spectrum whose peak locations along the x-axis are associated with the vibrational patterns distinct to a particular type of chemical bond. Peak (band) heights are measured in absorbance or % transmittance on the y-axis, and their position along the x-axis is a measure of radiation frequency, typically recorded in units of cm^{-1}. Once a spectrum is produced, identifying the composition of the sample then becomes a process of learning (or looking up) the functional groups that are associated with particular bands and determining how these functional groups together comprise a molecular structure.

Key Issues

Advantages of FTIR

FTIR is particularly well suited to investigating not only the composition of the types of materials that archaeologists are often interested in but also how these have transformed through time as a result of human or natural processes. Our understanding of site formation processes and artifact life histories has been enriched through research on the chemical signatures of bone and sediment diagenesis, degradation of organics such as silk proteins, and crystallinity shifts as clays and bone undergo thermal alteration, all through the application of FTIR techniques.

A general advantage of FTIR is the ease and rapidity with which samples can be prepared and spectra produced. FTIR may be applied to liquids and gases but most archaeological applications involve solid phase samples. The common sample preparation technique of creating a pressed pellet mixture of ground sample and a potassium bromide (KBr) matrix (see Weiner et al. 1993) is relatively easy to carry out. It takes only a few minutes to produce a spectrum whose band

positions, heights, and widths all relay information about the sample makeup. Moreover, only a few milligrams of sample are needed – or even micrograms if used in conjunction with an FTIR microscope – making the technique a good choice for use on trace compounds or rare objects (e.g., Doménech Carbó et al. 1996; Lluveras et al. 2010; Liu et al. 2011).

Finally, benchtop FTIR instruments are inexpensive relative to many types of high-tech analytical equipment. An "M series" instrument from MIDAC Corp. (CA, USA) currently (2011) runs about $20,000 (USD) – a good bargain for such a general utility analytical tool. Manufacturers have also made great strides in improving the ease of the instrument's physical transport for field applications. In the 1990s, pioneering efforts at on-site FTIR analysis for archaeology required daily hauling of a benchtop instrument (roughly the size of a trombone case but considerably heavier) into a remote cave site, where the machine was powered by a gasoline generator and draped in plastic sheeting for protection from dust (Weiner et al. 1993). The rugged miniaturized and even handheld portable instruments on the market today command roughly two to five times the price of a benchtop machine, placing them out of reach for many archaeologists. Many of these instruments are quite specialized, developed for niche markets like federal law enforcement. As consumer interest in portable FTIR instruments continues to grow, however, archaeologists may soon find it easy to conduct real-time analysis of archaeological materials as they are revealed through excavation.

Disadvantages of FTIR

FTIR has important limitations. Potential users should be aware that results can vary with sample preparation technique and the type of instrumentation employed (Coleman 1993). A particular nuisance that accompanies the use of KBr as a pelleting medium is its propensity to absorb liquid and atmospheric water. Unlike KBr, which is transparent in the mid-IR range, water produces bands that may overlap with those associated with the material of interest. Researchers must thus take care to keep the samples and instrument free of ambient moisture (e.g., Weiner et al. 1993). Partly for this reason, many scientists outside of archaeology have turned to other sampling techniques. Attenuated total reflectance (ATR) is one of the more popular but produces different spectra from those obtained with KBr. Data collected with an ATR accessory may be referenced to spectra produced using the standard KBr technique (Thompson et al. 2009; Smith 2011: 132–138), but archaeometrists have so far shown little enthusiasm in adopting alternative sampling methods (Thompson et al. 2009) as they work to build spectral reference libraries unique to the discipline.

A more specific problem regards the preparation of bone samples. Mineral crystallinity is one measure used to evaluate the extent of burning and other postmortem processes that bone has undergone (Stiner et al. 1995; Lebon et al. 2010). Surovell and Stiner (2001) have shown, however, that crystallinity is also affected by the intensity with which a bone sample is ground in preparation for KBr pelleting, but offer a protocol to standardize the procedure.

Applications

Below I offer examples of the array of archaeological problems to which FTIR can be profitably applied, drawing on representative publications that I hope will inspire the reader to consider how FTIR may be used in her own research. Many of these can be found in the *Journal of Archaeological Science*, a major publisher of archaeometry studies whose readership is international.

In a particularly noteworthy group of studies, researchers used FTIR to document the surprising extent to which archaeological deposits may become chemically transformed. Wood ash from prehistoric hearths and bone are two archaeological materials capable of delivering key information about past hominin behavior. FTIR analysis of Pleistocene sediments from Israel's Kebara and Hayonim Caves (Weiner et al. 1993, 2002) and Theopetra Cave in Greece (Karkanas et al. 1999) has revealed that both types of deposits are susceptible to severe diagenetic alterations in the complex chemical environments that caves

frequently support. In some areas of these sites, chemical alterations significantly reduced sediment volume by dissolving large deposits of fresh wood ash, leaving behind only relatively insoluble silica-rich bodies called silicious aggregates. In other areas, often in close proximity, diagenesis transformed bone and ash from their fresh, calcite-rich state into a sequence of intriguing minerals that can be identified using FTIR by their distinct phosphate structures (Schiegl et al. 1996; Stiner et al. 2001). The implications of diagenesis for taphonomy, site dating, and reconstructing site formation processes are significant and wide-reaching. FTIR has proven especially important in ongoing attempts to measure and improve our understanding of how bone diagenesis works. Research in this vein is likely to grow in the future, coordinated with studies aimed at reconstructing past diets and environmental conditions through the use of stable isotopes derived from well-preserved bone and tooth enamel (e.g., Wright and Schwarcz 1996; Lebon et al. 2010; Roche et al. 2010).

FTIR can also provide clues to artifact production sequences, such as the temperature ranges in which clay vessels were fired (Damjanović et al. 2011). These types of studies often require that researchers create their own reference spectra *de novo*. The investigators cited here, for instance, collected reference data by conducting experiments on the effects of thermal alteration on local materials using heating methods appropriate for the time period under investigation.

Finally, FTIR has important applications in provenance studies such as amber sourcing (Beck et al. 1965; Peñalver et al. 2007), materials identification (e.g., Lluveras et al. 2010), and conservation. To illustrate, Liu et al. (2011) were interested in identifying the types of fibers and dyes used in elaborately decorated textiles unearthed from tombs located along China's Silk Road. FTIR coupled with an FTIR microscope revealed amide bands particular to a particular form of silk protein, while complementary analyses including scanning electron microscopy and high-performance liquid chromatography (HPLC) allowed the researchers to examine the morphology of the fibers and identify the dyes used to tint them. Significantly, FTIR also revealed degradation of the textiles that had gone previously undetected. Excellent examples showing the range of materials and applications to which FTIR can be applied for conservation purposes can be found in Doménech Carbó et al. (1996).

A Note on Training

With a little practice, a user can learn to produce consistently high-quality spectra using ATR or KBr methods. Making meaning from these spectra, however, requires additional training and experience – as well as a good reference library of spectra. As suggested above, users may need to generate some of these comparative spectra on their own. Smith (1999) rightly describes the process of interpreting IR spectra as equal parts art and science, and his 1999 and 2011 texts are essential guides for users of all types. No book, however, can replace the experience of working alongside a skilled practitioner as one first learns to navigate the spectral landscape.

F

Fournier, Patricia

Velasquez S. H. Verónica
Instituto de Ciencias Sociales y Humanidades, Área Académica de Historia y Antropología, Universidad Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, Mexico
Department of Archaeology, University of Sheffield, Sheffield, UK

Basic Biographical Information

Patricia Fournier is a Mexican archaeologist, professor, and researcher at Mexico City's National Institute of Anthropology and History. Born on April 28, 1955, she completed her undergraduate degree at the National School of Anthropology and History in Mexico City (1985) under the supervision of Thomas H. Charlton and obtained her M.A. degree in anthropology from the University of Arizona (1989), where she worked under the supervision of Michael B. Schiffer. In 1995, she obtained her doctorate in anthropology at the National Autonomous University of Mexico. Her postdoctoral research was at the

Fournier, Patricia, Fig. 1 Patricia Fournier in 2012

Smithsonian Institution's Center for Materials Research and Education in Washington, DC, in 2003 under the supervision of Ronald L. Bishop. Her academic career began in 1980 working for the National Institute of Anthropology and History. By 1989, she was one of the main protagonists in the foundation of the first graduate program in archaeology in Mexico at the National School of Anthropology and History (Fig. 1).

Fournier has a vast experience in both fieldwork and analysis of archaeological materials. Throughout her career, she has directed and participated in historical archaeology research projects in diverse Mexican rural and urban sites as well as in Texas and New Mexico.

Fournier has received several distinctions along her career such as the Fulbright-LASPAU scholarship to pursue her M.A. studies in anthropology at the University of Arizona and the award for best archaeological undergraduate thesis in archaeology in 1985, as well as the award for the best research in archaeology in 1995 on behalf of the National Institute of Anthropology and History of Mexico. She has been an active member of the Society for American Archaeology serving as coeditor of Latin American Antiquity (1999–2002) and in the Committee on the Americas. She has also been an active member of the Society for Historical Archaeology; since 1999, she has served in the Advisory Editorial Committee for the journal *Historical Archaeology*, and she is a member of the Mexican Academy of Sciences. Since 2006, she is a research associate at the Archaeometry Program (National Museum of Natural History-Smithsonian Institution, Washington, DC) and an associate collaborator with the Arizona State Museum (the University of Arizona).

Major Accomplishments

It is not an easy task for a female archaeologist interested in the early modern period to catch the eye of local and international scholars in a field dominated by men and pre-Hispanic archaeology. This is an inherent quality of Patricia Fournier, one of Mexico's best representatives of historical archaeology who has raised the field to its highest levels in terms of impeccable scholarship, practical development, and theoretical understanding. As a faculty member and senior archaeologist at the National School of Anthropology and History, in 1992, she founded the specialization in historical archaeology and later in ethnoarchaeology and modern material culture studies.

Early in her career, Patricia Fournier became aware of the need to develop archaeological research of the historical periods in Mexico. This pioneer interest took her into the adventure of studying local and imported ceramics found in Mexico City which resulted in the foundational study *Evidencias Arqueológicas de la Importación de Cerámica en México, con base en los Materiales del Ex-Convento de San Jerónimo* (1990). Her interests in conducting research of historic sites were further shaped by Thomas H. Charlton with whom she collaborated in research projects that have had substantial impacts in Mexican historical archaeology, namely, on the study of indigenous and Hispanic ceramic traditions and technologies (e.g., Charlton et al. 2007).

Her vast interests and fascination for historical archaeology have taken her into the pioneer archaeological research of mining sites, rural settlements, and historic ceramic correlates for the understanding of commercial networks along the colonial Royal Road and Afro-descendant groups

(e.g., Fournier 1999; Fournier and Charlton 2008; Fournier and Blackman 2010). Moreover, her research on ceramics has resulted in a range of works related to production and consumerism during the colonial and independent periods in Mexico, a topic that had been overlooked in Mexican archaeology. Those works now serve as a foundation for subsequent studies (Fournier 1997). Recently, she has been collaborating with scholars from the Smithsonian Institution utilizing archaeometric techniques in the study of majolica and glazed wares (e.g., Blackman et al. 2006; Fournier et al. 2009), identifying production centers and addressing commercialization, consumerism, identity, display of wealth, and the impact of colonizing processes in the lives of indigenous and European groups. The results derived from these research projects have changed significantly previous conceptions on the production origin of Mexican ceramics and have enabled the reframing of previous assumptions on exchange, technology, production, and consumerism.

The vast trajectory of Patricia Fournier has established an archaeological tradition that has paved the way for students and scholars alike. It pronounces the importance of studying historical remains through a scientific approach. Moreover, she stresses the relevance of incorporating concepts related to site formation processes, ethnoarchaeological techniques, experimental archaeology, material culture studies, the dynamics involved in social complexity, symbolic anthropology, and an emphasis on the use of primary and secondary documentary sources in archaeological studies. Her innate ability as a researcher and professor since 1984 has enabled her to prepare generations of students and continues to inspire many in Mexico and elsewhere to follow her steps into the fascinating adventure of unraveling the recent past.

France: Field Method Origins

Nathan Schlanger
Trajectoires, Maison Archéologie & Ethnologie (MAE), Nanterre, France

Brief Definition of the Topic

It was through the innovative application of sound field methods that Jacques Boucher de Perthes (1788–1868), a customs official in northern France, contributed decisively to the establishment of human antiquity. He argued that proof of an object's antiquity resided first and foremost in "its surrounding [*entourage*] and the place where it is encountered" (Boucher de Perthes 1847: 34, 178, 181). By insisting on such principles of stratigraphic position and integrity, Boucher de Perthes could argue that the artificially shaped flint *haches* he found beneath meters of undisturbed gravels in association with fossil bones of extinct species were therefore of infinitely ancient age, long before the Biblical Flood (thus *antediluvian*). While these claims had met with skepticism, a dramatic reversal of fortune occurred in 1859 with the visit to the region of two English scientists, the wine merchant and geologist Joseph Prestwich (1812–1896) and the paper manufacturer and numismatist John Evans (1823–1908). Besides conducting a thorough audit of the context of discovery, the visitors also took the unprecedented step of having a photograph taken, on the 27th April 1859, of an in situ hand axe embedded in a quarry section at Saint-Acheul (Fig. 1). This very first use of the photographic medium for stratigraphic demonstration not only confirmed human antiquity but also served to shift the onus of archaeological demonstration from rhetoric and personal reputation to methodically documented observation (Gamble and Kruszynski 2009).

Meanwhile in the South of France, cave sites were being explored by Édouard Lartet (1801–1871), a lawyer and paleontologist from Sarlat. The *Reliquiae Aquitanicae* he published together with banker Henry Christy in the mid-1860s highlighted the rich potential of these caves, with their well-preserved faunal remains as well as flint and bone tools, for establishing a sequence of periods when rhinoceros, mammoth, and reindeer roamed. This research was soon brought together at the newly created *Musée des antiquités nationales* by the engineer and curator Gabriel de Mortillet (1821–1898). By means of their association with geological strata and fauna, de Mortillet defined the artifacts themselves as fossil types, so establishing the succession of Acheulean, Mousterian, Solutrean, and Magdalenian periods, named after the French sites where they were defined. While undergoing many revisions and expansions over the years, this classificatory system still remains today as the cornerstone of Paleolithic archaeology.

France: Field Method Origins, Fig. 1 A quarry worker showing the location of an in situ hand axe, Saint-Acheul, 27th April 1859 (Photograph by C. Pinsard, albuminated paper. Courtesy of Bibliothèques d'Amiens Métropole, Ms 1370.f.33)

This development of vertical investigation in France was followed in the 1960s by the development of the horizontal (*décapage*) method of

F

excavation pioneered by the ethnologist, technologist, and prehistorian André Leroi-Gourhan (1911–1986. See Audouze and Schlanger 2004). It was not of course without precedents. In the loess plains of Central and Eastern Europe, from Dolní Věstonice in Moravia to Kostenki in Russia, Upper Paleolithic habitations and mammoth-bone huts had long been identified and excavated through investigations in open area. Fluent in Russian, Leroi-Gourhan was well aware of these studies, though not necessarily of their historical materialist underpinnings. Drawing on his own paleontological and anatomical expertise, he himself had undertaken since the 1940s (e.g., at Les Furtins) the meticulous recording of human burials, in their sequence of inhumation and deposition, thus pioneering the subfield of funerary archaeology.

These initiatives converged in 1964, at the excavation of an extremely well-preserved hunter-gatherer occupation site in the sand quarries of Pincevent, south of Paris. This series of Magdalenian camps (c. 12,500 BP) represent the seasonal halts of reindeer hunters, next to a ford on the R. Seine (Bodu et al. 2006). The dedicated excavation methodology deployed there by Leroi-Gourhan and his team included the meticulous exposure and millimetric stripping (sometimes with dental tools) of vast surfaces of finds and features, left for as long as possible in situ to be drawn, recorded, photographed, and thoroughly documented, square meter by square meter (Fig. 2). This small-scale plotting of the distribution of the finds – flint and bone remains – made it possible to map the functional and spatial relations between such features as hearths, tents, butchery areas, knapping areas, and dumps and led to the identification of vanished structures. Moreover, the extensive refitting of flint débitage and tools at Pincevent (and subsequently at other sites in the region) not only served to retrace the spatial and functional biographies of tools and thus grasp "precise moments in the remote past" – they also made it possible to reconstruct the technical processes of Upper Paleolithic flint tool production and use, thus contributing decisively to the development and demonstration of the *chaîne opératoire* approach in prehistoric archaeology.

Leroi-Gourhan's concern with the minutiae of "prehistoric ethnology" led subsequently to ongoing comparative research in Arctic areas – where it was to converge with ethnoarchaeological studies by Lewis Binford and others on hunter-gatherer campsites in Alaska, as well as Australia and Southern Africa.

France: Medieval Archaeology

Bailey K. Young
History Department, Eastern Illinois University, Charleston, IL, USA

Introduction

In 2006, when a congress of the *Société d'archéologie médiévale* (*SAM*) reviewed the history of the field, about 500 people in France were being paid to work "for the benefit of medieval archaeology," which accounted for 25–30% of all archaeological activity in the country. The research sector was vigorous: between 1991 and 2008, for example, 103 research projects recognized by the *Centre national de la recherche archéologique* (CNRA) were under way – with most activity conducted by professionals from the "preventive archaeology" sector. The lion's share of publication, however, was done by researchers based in the universities and/or the *Centre national de la recherche scientifique* (CNRS). Between 1999 and 2008 some 377 works treating of medieval archaeology (168 of them almost exclusively) appeared; 37 of the 69 authors who published at least twice from 2002 to 2005 were University or CNRS. The next largest group, 16, belonged to the *Institut national de recherches archéologiques préventives* (INRAP), the public archaeology operator which since its creation in 2002 has been responsible for most excavation in France. The phenomenal growth of highly professional, publically funded archaeology over the past 30 years has fostered methodological innovation and improvement (Chapelot 2010: 393–435). Two recent works aimed at a popular audience offer well-illustrated examples of preventive excavations (Burnouf 2008; Catteddu 2009). Aimed at students and scholars, the *Manuel d'archéologie médiévale et moderne* stresses how our perspectives on the Middle Ages as a whole are being reshaped by the results of expanded and improved fieldwork integrated with the analysis of written, iconographic, and other surviving sources (Burnouf et al. 2009).

F

Definition

Traditional usage deriving from written sources defines the Middle Ages as the millenium between the Fall of the Western Roman Empire (CE 476) and the Renaissance (c. 1500). Recent research incorporating archaeological data blends the earliest phase with a new chronological period labeled Late Antique, already transforming the Roman world by CE 300, when the influence of barbarian groups and of Christianity had become significant (Catteddu 2009: 6–23). Archaeology strongly supports the view that by the twelfth century, notably in France, major social, political, and environmental changes were under way that were to define the basic structures of Europe in the early modern period, before the transformations wrought by industrialization. Joëlle Burnouf would thus blend the Renaissance into a long second Middle Ages that extends throughout the sixteenth century and even beyond (Burnouf 2008: 6–13).

Historical Background

Origins of Medieval Archaeology in France (c. 1830–c. 1960)

Before about 1970 medieval archaeology had no institutional standing and no generally recognized identity in theory or practice. There were predecessors going back into the first half of the

nineteenth century: Merovingian funerary archaeology and monumental religious (essentially Christian) archaeology (Young 2001). Both were tributary to paradigms derived from established academic disciplines. Merovingian graves, identified by artifacts frequently placed with the deceased (notably weapons, personal ornament, ceramics), were thought to reflect the settlement of ethnically distinct "barbarians" who took power, as the narrative derived from written sources had it, in the western provinces of the former Roman Empire. From the 1850s, marked by the excavations and publications of the Abbé Cochet in Normandy, through the 1950s when Edouard Salin closed his long career with four volumes synthesizing fieldwork and laboratory analysis, many thousands of graves were excavated, at times by amateurs with some sense of method, but many more were plundered or simply destroyed by development (Périn 1980). Following the creation of the *Monuments Historiques* in 1830 and the founding by Arcisse de Caumont of the *Société française d'archéologie* and the *Bulletin monumental* in 1834, the decision to preserve the churches (and a few castles) of medieval France led architects like Viollet-le-Duc and art historians to develop methods to study the historical development of these monuments where some excavation might be combined with stylistic analysis to guide restoration (Barral I Altet 1991). In the twentieth century this tradition was continued not only by *Monuments Historiques* architects like Jules Formigé but further developed with long-term projects by the American art historians Kenneth Conant at Cluny and Sumner Crosby at Saint-Denis concerned primarily with understanding the history and the influence of these major monuments (Young 2001).

Emergence of Medieval Archaeology (c. 1960–c. 1980)

As a discipline and practice "modern" medieval archaeology in France has developed over the past 40 years (Burnouf 2008: 12–24; Chapelot and Gentili 2010). Its godfather was Dean Michel de Boüard of the University of Caen, who created there the *Centre de Recherches Archéologiques Médiévales* (CRAM), linking it also to the CNRS, with the consequence that systematic, ongoing research excavation as well as salvage operations could enjoy permanent laboratory support. As he was also regional director of historical antiquities, the organism of the Ministry of Culture responsible (since 1942) for overseeing all excavation, de Boüard was able to develop a model of practical cooperation among archaeological actors and consumers which dynamized research and raised overall standards. Himself a pioneer of the archaeology of castles (Chateau de Caen, Doué-la-Fontaine, early *motte* sites), he also created in 1971 the scholarly journal of reference, *Archéologie Médiévale*, published the first textbook (de Boüard 1975), and founded the *Société d'Archéologie Médiévale* (1983). His students and associates conducted innovative and rigorous Merovingian cemetery excavations in the Caen region, notably, at Frénouville, the first totally excavated and published necropolis (Pilet 1981) complemented by a complete study of the physical anthropology (Buchet 1978). The second University/CNRS medieval research center working closely with the public authorities was created in 1967 by Gabrielle Démians d'Archimbaud at Aix-en-Provence (*Laboratoire d'Archéologie Médiévale Méditerranée*, or LAMM) with a particular focus on ceramics and, later, glassware. She also launched the first long-term research excavation of a medieval settlement at Rougiers, near Marseille (Démians d'Archimbaud 1981). The third research pole developed in Paris, where Jean-Marie Pesez, working with historians of the *Annales* school based at the future *École des Hautes Études en Sciences Sociales* (EHESS) launched in 1965 at Dracy (Côte d'Or), a long-term, multisite research program involving deserted villages (inspired by Wharram Percy in England), later expanded along with his pupils to other types of rural settlement of the later Middle Ages (Pesez 1998). He founded in 1969 the *Groupe d'archéologie médiévale* (GAM), today directed by Jean Chapelot. Beginning with the excavations from 1968 to 1972 of the pottery workshops at the Carolingian site of Saran (Loiret), Chapelot launched systematic research into the production, technology, and distribution of medieval ceramics.

Heightened awareness of the accelerating destruction of the archaeological heritage by development favored, in the 1970s, the growth of salvage archaeology conducted by better-trained teams accountable to public authorities (Chapelot and Gentili 2010). The creation in 1973 by the Ministry of Culture of the *Association française d'archéologie nationale* (AFAN) as a vehicle to publically fund excavation by paying shovel bums on limited contracts provided a flexible workforce. Medieval urban archaeology emerged as a major enterprise for the first time in Douai, the first town to salary a full-time archaeologist (Pierre Demolon, in 1971), and in Tours, where Henri Galinié returned from working under Martin Biddle at Winchester to win municipal support for an urban archaeology unit (*Laboratoire d'archéologie urbaine)* which would host the first national colloquium on urban archaeology in 1980 and provide the basis for the *Centre national d'archéologie urbaine* (CNAU) in 1984. The longest ongoing urban program began as a salvage operation by Olivier Meyer and Nicole Meyer-Rodrigues in 1973 in Saint-Denis, just north of Paris; it expanded in 1982 into a municipal archaeology unit as well as a field school for various branches of the University of Paris and a beacon for "civic archaeology", developing since 1998 a "*Parcours historique*" as a permanent feature of the renovated city center. By 2008 about 13% of the medieval town had been seen in the course of some 160 operations, with about 3%, including key areas adjacent to the famous abbey church at the core, systematically excavated with the open-area methodology originally borrowed from Britain, and in use here since the 1970s (Meyer-Rodrigues 2010).

Other long-term research projects which got under way in the 1970s concerned the transition from Roman towns to Christian episcopal cities, with very active excavation programs in Grenoble (M. & R. Colardelle) and Lyons (J-F. Reynaud) inspired by the pioneering work of Charles Bonnet in Geneva and the study of religious monuments and cemeteries in Burgundy (Sapin 2010). The excavation of an early castral site at Andone (Charente) by André Debord would provide a model archaeological case study of the historians' "feudal mutation" (Bourgeois 2009), while Michel Colardelle's exploration of a timber-built early eleventh century settlement, subsequently submerged under an Alpine lake at Charavines (Isère), was innovative for its underwater excavation methodology and its multidisciplinary environmental perspectives (Colardelle and Verdel 1993). Merovingian archaeology was renewed with the creation in 1979 of the *Association française d'archéologie mérovingienne* (AFAM) and Patrick Périn's development, with the help of René Legoux, of more precise and reliable artifact chronologies and of innovative tools of topochronological analysis (Périn 1980).

Nonetheless, a 1976 report to the French parliament on the state of national archaeology found it alarmingly undermanned and underfunded in the face of the challenges posed by accelerating development. Medieval archaeology was particularly badly served. Of the 198 archaeologists paid by the CNRS, only four were medievalists; indeed, only 74 worked primarily in France. There were rather more in the universities, 16 as compared to 28 specialized in earlier periods. For France as a whole, Jean Chapelot finds that there were then 27 specialists for the Middle Ages compared to 180 concerned with the Gallo-Roman and prehistoric eras. Professional infrastructure overall was weak. Of France's 44 archaeological circumscriptions, only 12 were then headed by salaried directors, who were aided by 23 salaried assistants. Not one of them was a medievalist (Chapelot and Gentili 2010: 11–14).

Maturity and Expansion in the Age of Preventive Archaeology (1980–2010)

The year 1980, decreed by the French president as Heritage Year (*l'Année du Patrimoine*), marked the beginning of a phase of phenomenal growth for archaeology in France, with the creation of the *Sous-Direction de l'archéologie* in the Ministry of Culture, a sign of government engagement. The passage of a law requiring an environmental impact study in 1976 came to normalize the principle that developers pay for preventive archaeological study; public funding for research was also increased massively (Chapelot and Gentili 2010:

13–14). Over the 20 years from 1989 to 2009, the number of archaeological operations increased by 60% (and they tended to encompass much larger areas), the number of people employed multiplied by 4, and funding multiplied by 7 (Chapelot 2010: 396–398). The last two decades of the twentieth century also saw much infrastructure development in France, with new high-speed lines (TGV-Nord), new autoroutes, and massive redevelopment in core urban centers (Paris Grand Louvre is the outstanding example), peri-urban areas (Marne-la-Vallée and Eurodisney east of Paris; Roissy airport to the north), and rural areas as well, providing opportunities for salvage – now called preventive – archaeology on a scale hitherto unimaginable. The challenges encouraged methodological innovation carried out by an increasingly professional workforce, their status strengthened when in 2002 AFAN was replaced by INRAP (*Institut nationale de recherches archéologiques préventives)* as the primary archaeological operator in France. The medieval component has been particularly dynamic (Chapelot and Gentili 2010: 14–19). In 2008 some 25–30% of all archaeological operations were medieval, with around 500 people salaried full time at work on some aspect of medieval research. Of these about 15% were based in the universities or the CNRS (they account for the lion's share of publication); more than a third of the total worked for INRAP. Between 1991 and 2008, 103 research projects concerning the Middle Ages received national funding, about half of them directed by University/CNRS scholars, with the other half directed by INRAP or other public archaeological authorities (Chapelot 2010: 393–404).

One field spectacularly transformed by the change in scale of operations and multidisciplinary character of the research teams is the study of the rural landscape. In 1979 only four rural settlements had been excavated in all France; in 1991 the total was 155, a quarter of these in the Ile-de-France alone. The scale of excavation jumped from a norm of a few hundred square meters at best before 1985 to over 4 ha at La Grande Paroisse by 1986 and in the 1990s to over 10 ha at Serris and Villiers-le-Sec (Chapelot and Gentili 2010: 17–19). Perspective shifted from an emphasis on the individual settlement – or even certain of its phases – to the dynamics of spatial organization over time, as at Montours in Brittany where the INRAP team studied how a landscape was structured in Carolingian times through the interaction of four poles of settlement (Catteddu 2001). The traditions of architectural history have given rise to a new methodology for studying the modification over time of standing buildings, *l'archéologie du bati*, which, conjoined with excavation, has enhanced our understanding of the medieval town as the direct ancestor of the modern city and the complexity of its role as a site of the material and ideological competition of local and regional elites (Burnouf 2008: 69–87; 102–111). Before preventive archaeology the recovery and post-excavation conservation of artifacts (to say nothing of ecofacts) was often haphazard; today the millions of tons of objects – ceramics, metal, glass, bone, and construction materials – preserved are testimony, as Joëlle Burnouf stresses, to a medieval industrial revolution that prepared the one better known to historians, resulting in an expansion and refinement of products available that prefigures consumer society (Burnouf 2008: 118–155).

With that founding at Caen in 1983 of the *Société d'Archéologie Médiévale (SAM)*, the new discipline entered a phase of maturity. Beginning with the theme of ceramics in 1985, the SAM has organized ten international congresses (the latest, at Arles in 2012, focused on the horse) and regularly published their proceedings. A review of these volumes, of *Archéologie Médiévale* with its valuable annual gazetteer of sites under excavation, of the major regional journals, the monographs published in the nationally supported series *Documents d' archéologie française (DAF)*, by the *Association française d'Archéologie mérovingienne* (AFAM), and by private publishers, confirms the vitality of the field today (Faure-Boucharlat and Flambard Héricher 2010).

Key Issues/Current Debates

1. Migration, ethnic identity, and Christianization. Authors from the Abbé Cochet through E. Salin accepted as self-evident the notion that

the funerary practices of Late Roman and Merovingian times reflected the ethnic identity and religious ideas of the Romans and barbarians. Since the 1970s this view, still tenacious in popular literature, has been challenged by interpretations which emphasize social, economic, and cultural factors and area more critical of the written sources from which the older view derives. Ethnographic, folklore, and cultural studies have helped show that "Christianization" was not a monolithic process, that funerary practice could vary considerably even within Christian contexts and similar or even identical symbols could have a variety of meanings, often inaccessible. Debate continues regarding the establishment of Christian infrastructure, such as rural parish churches, monasteries, in the earlier Middle Ages, or chapels of mendicant orders later on, and their role.

2. The urban phenomenon. The caricatural view, based on a few written sources and still commonly held in the 1960s, was that Roman towns in Gaul brutally declined and fell to barbarian invaders, leaving a largely primitive, Dark Age landscape. Excavation now suggests that almost all survived, transformed into Christian capitals, though debates continue on the nature and function of these towns in earlier medieval times, including how to interpret the strata of dark earth often encountered. The role of "Dark Age" emporia, long overlooked, is now posed by the Quentovic research program. Another older notion, forcefully argued by the historian Henri Pirenne before WWII, of a revival of towns and trade in NW temperate Europe around the year 1000, needs considerable nuancing in the light of recent research. Discussion today stresses the densification, apparent by the twelfth century, of a complex urban network, hierarchically organized, in the context of rapid demographic and economic growth and the self-affirmation of emerging elites confronted with growing royal and princely power.
3. The village and the rural landscape. The village has long been viewed as a key artifact of medieval civilization, its origins and development a matter of research and ongoing debate. Historians like R. Fossier argued in the 1970s that it was largely a post-Carolingian creation, an aspect of the "feudal mutation" associated with the imposition of lordly power, village churches, and serfdom. Earlier medieval settlements, he thought, were poor, fluctuating, and unstable. The large-scale preventive excavations since the 1980s have provided an enormous amount of new data still being analyzed, but it is already clear that Carolingian and Merovingian settlements were more complex and varied than had been appreciated and that Christian infrastructure sometimes appeared well before the year 1000. The case for the plausibility of continuity from Late Roman, Roman, or even Iron Age times for key settlements appears stronger. The debate will likely continue, since much of the archaeology of rural settlements concerns those which were subsequently abandoned and that excavation of permanently occupied villages on any significant scale has not been possible.
4. Fortification, castles, and feudal mutation. A key tenet of the "feudal mutation" hypothesis, based mostly on written sources, is that the extensive network of rural fortifications whose visible remnants are the stone castles surviving today was largely developed in the post-Carolingian times with the spread of lordship, whereas earlier villages and elite residences were usually unfortified. The twelfth century saw new fortifications around towns, rebuilt and expanded as these grew in the following centuries. Excavation since WWII has provided much new data about the fortification of the reduced core areas of Late Roman cities and their continuing use throughout the earlier Middle Ages. More surprising is the recent discovery in some regions, such as the Languedoc and the Massif Central, of Late Antique or early medieval fortified rural sites subsequently abandoned (Schneider 2010). Much new data has also emerged about the construction of earthen mottes topped with timber ramparts and towers in Normandy, Flanders, and similar regions in the tenth to twelfth centuries, but Annie Renoux warns that these need

to be understood in the context of a wide variety of elite residences, more or less fortified urban and rural (Renoux 2010). Two very different types of fortified sites from the time of the now contested "feudal mutation" at the turn of the millenium are now known through the publication of systematic modern excavations followed up by specialist studies of artifacts and ecofacts: the palisaded Alpine lakeside settlement of Charavines (Colardelle and Verdel 1993) and the stone *castrum* of the Counts of Angoulême at Andone (Bourgeois 2009).

5. Environment, climate, economy, infrastructure, and society. Forty years ago a strong contrast was drawn between, on the one hand, a primitive, even autarchic, earlier medieval landscape peopled (sparsely) by poor peasants living in villages surrounded by forests, marshes, and wastelands and surviving (barely) with crude technologies and, on the other, the dramatic expansion after c. 1000 of population and production driven by innovative technologies, with massive land clearances and vigorous exchange networks prefiguring the early modern world. Though the twelfth century now appears more than ever as an irreversible threshold, the picture needs much nuancing. The early medieval countryside now appears more the result of the successful adaptation of environmentally savvy local communities to changed conditions, with climate deterioration (not even on the radar 40 years ago) perhaps as much a factor as political changes. Fluvial archaeology, another new field, reveals a more complex and sophisticated infrastructure of exchange than hitherto suspected, and the excavation of emporium sites abroad, like Dorestad in Holland and Ribe in Denmark, is prompting research in France around sites like Quentovic. For Joëlle Burnouf the "second Middle Age" inherited many key features from the earlier centuries (transportation networks, rural landscapes already largely cleared and structured, metal-working techniques perfected since Iron Age times) and carried them to unprecedented levels of development under the favorable conditions of the climatic optimum. When in the fourteenth century the beginning of the Little Ice Age conjoined with the more abrupt brutality of the Black Plague so rooted were the technologies and productions, the elite-dominated but flexible social structure with their nuanced displays of power and prestige upholding religion-infused ideologies that the lifeways attested by archaeology reflect not catastrophe but continuity, a cultural resilience that carries right through the "Renaissance" of art historians right through the sixteenth century (Burnouf 2008: 102–110, 138–159).
6. Technologies and the medieval industrial revolution. Research into the production and distribution of ceramics was the first subfield of medieval industrial production to emerge; more recently new research has focused on glass manufacture, mines and quarries, iron working, energy production through wind and water, salt extraction and distribution, brick and tile and timber as construction components, products made from animal matter such as leather and bone, and other organic materials (the latter aided by methodologies favoring the recovery and conservation of artifacts from water-saturated zones). Altogether they confirm an unprecedented change in the scale of production during the later Middle Ages and, hence, an impact on lifeways and expectations which prepared the later, better-known Industrial Revolution (Burnouf 2008: 118–136).

International Perspectives

In the nineteenth and twentieth centuries, French Merovingian archaeologists were often in contact with colleagues also excavating barbarian graves in England, Belgium, Germany, Switzerland, and even Russia but were little influenced by the pioneering settlement excavations of such sites as Gladbach, in Germany, before WWII. The American art historians excavating religious monuments at Cluny and Saint-Denis shared the same essential training and methodologies and perspectives as their French peers (Barral I. Altet 1991). International influences

became notable and decisive in the postwar period. *Medieval Archaeology*, created in 1956, was the model for *Archéologie Médiévale*, and Michel de Boüard's engagement in castle research soon led to the regular international meetings and publications of the *Chateau Gaillard* group. Wharram Percy and the deserted villages project influenced both G. Demains d'Archimbaud and J.-M. Pesez to launch settlement excavation in the 1960s, and in that decade Paul Courbin encouraged the use of the Wheeler method in France. Pesez and the EHESS group developed strong and regular relations with the school of Polish archaeologists, adopting their methods for excavating timber-and-earth structures (Chapelot and Gentili 2010: 4–8). The innovative approaches to studying the internal dynamics, chronology, and socioeconomic and cultural implications of Merovingian cemeteries developed by German scholars like Kurt Böhner and Joachim Werner became familiar in France from the 1970s through the work of Patrick Périn (1980). At the yearly AFAM conferences since 1979, presentations of ongoing research by British, German, Dutch, Scandinavian, East European, Italian, Spanish, and even American scholars have been a regular feature. The American "New Archaeology," however, has had only limited influence on French archaeologists; medievalists, in particular, used to working collaboratively with colleagues in the historical disciplines, have been little tempted by calls for rigid separation.

Since the 1970s a growing number of close-knit international groups of scholars have collaborated on common projects. The pioneering excavations of Charles Bonnet, cantonal archaeologist of Geneva, on the development from Roman times of the Christian episcopal center in relationship to its countryside inspired similar programs led by Michel and Renée Colardelle in Grenoble and Jean-François Reynaud in Lyons (as well as by Rinaldo Perinetti in Aosta); these archaeologists met regularly to follow one another's work and together organized the 1985 international congress of Christian Archaeology which visited all these sites. Their work fit into the larger project on the *Topographie chrétienne des cités de la Gaule*, launched in 1974 by N. Duval, P-A. Février, and Ch. Pietri, which has since that time been publishing standardized notices, developed through regular and rigorous discussion by the participating scholars, of the Christian monuments and religious topography from all the Gallo-Germanic provinces. Christian Sapin cites the influence of Joseph Mertens (Belgium), William Rodwell (England), Hans Sennhauser, and Charles Bonnet (Switzerland) in the recent development of religious archaeology in France; since 1986 the *Centre d'Études médiévales* he founded in Auxerre has sponsored research on cathedrals, abbeys, funerary churches and cemeteries, and other religious monuments throughout Burgundy (Sapin 2010). The American archaeologist Harry Titus (Wake Forest University) collaborated on the study of the Auxerre cathedral using nondestructive, digital-based laser methodologies. Since 1982 Clark Maines (Wesleyan University) and Sheila Bonde (Brown University) have been excavating the abbey of Saint-Jean-des-Vignes in Soissons in the context of an interdisciplinary, international study of medieval monasticism (MonArch project). The strong influence of English examples on urban archaeology, most notably through the efforts of Henri Galinié at Tours, has been noted above. Fluvial and coastal archaeology developed in France after the International Waterfront Archaeology conference in London in 1981. English and Belgian archaeologists are associated with French colleagues in an ongoing study, coordinated by Laurent Verslype of the *Université catholique de Louvain*, of the Canche Valley where Quentovic, a major "Dark Age" emporium site, once flourished.

In the age of preventive archaeology and the World Wide Web, Medieval Europe has emerged as the focus of an international research community. French researchers were active in the first three congresses at York (1992), Bruges (1997), and Basel (2002); the fourth congress, organized by Joëlle Burnouf, was held at the Sorbonne in Paris in 2007.

Future Directions

Writing the conclusion to the 2006 SAM colloquium, Jean Chapelot stressed that the remarkable

growth of medieval archaeology since 1980, the new fields of inquiry and the robust infrastructure it has developed, should not arouse ambitions of disciplinary autonomy (Chapelot 2010: 431). As Michel de Boüard stressed 40 years ago (DeBoüard 1975) and Joëlle Burnouf and her coauthors reaffirm (Burnouf et al. 2009), the Middle Ages offers archaeologists the challenge of a field which, to a much greater extent than earlier periods in Europe, is richly furnished with a great variety of surviving written, iconographic, and architectural "documents." With their specific methodologies so much enhanced by the progress of the past generation, archaeologists must continue to work closely, collaboratively, and creatively with textual scholars, art historians, epigraphers, anthropologists, geographers, and of course scientists concerned, for example, with the history of plants and animals, human populations and disease, climate and environment, in order to broaden and enhance our understanding of the crucial millennium which gave birth to the modern world.

France: Promotion of Archaeological Heritage

Xavier Delestre
Institute direction régionale des affaires culturelles de Provence-Alpes-Côte d'Azur, Aix-en-Provence, France

Introduction

The conservation of archaeological remains in France is part of a process of heritage promotion and education. It is also directly involved in the Tourism sector of the territories and their reputation.

As they are often called upon by heritage preservation associations and the public at the time of discovery and relayed by the media, these presentations of archaeological remains have always been exceptional for various reasons: the exhumed remains are extremely fragile, their readability is complicated by the superposition of remnants over many periods, the costs of investment and maintenance are very high, and they are incompatible with development plans.

Definition

We can estimate that in France the number of surveys leading to a sustainable promotion, in one form or another, of substantial archaeological heritage is in the low hundred. In the sites corpus, we can distinguish between two main types: open-air sites and crypts.

Within these groups, there are sites where access is fee paying with the possibility of guided tours for some. A few of these heritage sites benefit from a protection as Historical Monument (registered or listed), and sometimes they can even benefit from international recognition, directly or indirectly (UNESCO).

Examples

"Open-air" sites: for the Prehistory, we will mention as an example the Neolithic megalithic site of Carnac (Morbihan). For historical periods, especially in urban areas, the "garden of remains" of the Centre Bourse in Marseille (Bouches-du-Rhône) is an archaeological conservation area of nearly 1 ha in direct relation with a large history museum of the city.

It should be noted that this achievement is recognized in the national history of archaeology as a major event since it is the result of a political compromise achieved during the 1970s between the decision to build modern constructions in the heart of the oldest town in France and the decision to conserve highly significant Greek, Roman, and Medieval remains (port and fortifications).

Some presentations are limited to a consolidation of ruins in the state they were in after excavations. In this regard, the site with the most extensive archaeological remains, listed as Historical Monuments in France, is that of Vaison-la-Romaine (Vaucluse) with an area of more than 8 ha.

In the south of France, many archaeological sites are open to visitors, of which several are oppida, in Ensérune (Hérault) and Entremont (Aix-en-Provence, Bouches-du-Rhône), for example, or ancient cities like Glanum (St. Rémy-de-Provence, Bouches-du-Rhône) and Vaison-la-Romaine already cited.

Other sites open to visitors are still undergoing more or less substantial research programs, with the example of the Bibracte site (Mont Beuvray) bordering the regional departments of Saône-et-Loire and Nièvre. This undeniably increases the public's interest and therefore attendance at the site.

The visit can be extended to the experimental archaeology structures like at the European Park Bliesbruck-Reinheim (Moselle) or at Saint-Romain-en-Gal (Vienna) with the reconstruction of a vineyard and elsewhere to museographic installations (Cimiez, Nice (Alpes-Maritimes); Bavay (North)).

In recent years, several sites have been given prominence right after the excavations on the site with the construction of a museum space, for example, in Languedoc-Roussillon Loupian (Hérault) and Sallèles-d'Aude (Aude). The presentation of the ruins can also be enhanced by markings in the soil and soil treatments (colored gravel, grass) to facilitate the easy reading of plans. Only the site of Glanum (Saint-Rémy-de-Provence, Bouches-du-Rhône) has been the object, about 20 years ago, of a life-size anastylosis for the angle of an Augustus temple erected on the side of the forum.

Archaeological crypts make up the second group. The most monumental example is that of the Grand Louvre (Paris) with pits from the fortress of Philippe Auguste and Charles V. They were brought to light between 1983 and 1985. These archaeological crypts primarily show the vestiges from the Gallo-Roman or Medieval period. For this latter period, these are essentially religious relics. Among the most important recent achievements worth mentioning are the crypts of churches of Saint-Laurent de Grenoble (Isère), Saint-Raphaël (Var), and Digne-les-Bains (Alpes-de-Haute-Provence) and most recently the one in Nice (Alpes-Maritimes) made during the construction of a tram line to showcase modern and medieval fortifications. This crypt is the largest built in France after the Louvre in Paris.

To these two main categories, we must also add, in recent years, facsimiles or virtual tours of major World Heritage sites that are prehistoric caves. These initiatives allow a large number to discover these remarkable sites, where visits are prohibited for conservation reasons. The most representative example is being that of Lascaux II (Dordogne).

Finally, on this theme of the promotion of archaeological heritage, we must not forget the 20 or so archaeological parks, or archaeosites, that offer the public the possibility to visit educational reconstructions, relating to one or several periods, like, for example, the site of Aspanio (Villeneuve d'Asq, Nord).

Franchthi (Greece), Agriculture and Domestication At

Malisony Lisa Grasso
Department of Historical Studies, School of Humanities, University of Turin, Turin, Italy

Introduction

Franchthi (37° 25′ 20.90″ N, 23° 7′ 52.73″ E) is an archaeological site in Argolide, in the Southern part of Greece. It is one of a kind in Greece since it shows traces of human presence starting from the Upper Paleolithic (20,000 B.C. or even earlier) until the Final Neolithic (3,000 B.C.). The site is located in a cave in the South Western Argolide, in a small bay not far from the modern village of Kilada (see Douka et al. 2011).

The chronological sequence is determined on the basis of a homogeneous series of radiometric dating of the various levels of the stratigraphic deposit. The most ancient sample has been dated 20,000 B.C., another finding goes back to the Middle Paleolithic. The lowest layer, dug at present, has been dated around 35,000 and 30,000 years ago.

The site shows several stages of occupation: Medium Paleolithic, 35,000–30,000 years ago; Upper Paleolithic, 20,000–8,300 B.C.; Mesolithic, 8,300–6,000 B.C.; Lower Neolithic, 6,000–5,000 B.C..; Medium Neolithic, 5,000–4,500 B.C.; Upper Neolithic, 4,500–4,000 B.C.; and Final Neolithic, 4,000–3,000 B.C (see Farrand 2000).

Key Issues

The site was excavated between 1967 and 1979 by the American Mission of Indiana University, and the mission was led by Prof. T.W. Jacobsen, Professor of Classical Archaeology and Classical Studies at Indiana University. The excavation lasted almost 10 years and showed a continuous and long lasting human presence, the longest founded in the whole Greece. From 1979 until today, many scholars have continued to analyze the numerous findings discovered during the years of the excavation (see Douka et al. 2011; and for excavations see Farrand 2000).

From the studies, it has emerged that the cave of Franchthi must have been further away from the coast for most of its history. There was in fact a coastal plain that was slightly submerged during the occupation. This change was due to the progressive rise of the sea level.

In the Upper Paleolithic (20,000–8,300 B.C.), the people who were in the cave were probably hunters and gatherers, they occupied the site just seasonally. In this period in fact people would not stay in this site during the winter season. Before 11,000 B.C. there is no certain evidence of the cultivation of plants. It seems that the presence of seeds of plants from the family of Boraginaceae is due to the use of making pallets to sleep on or to the extraction of a colored pigment from their roots. Starting from 11,000 B.C., the first plants grown were lentils, vetch, pistachio, and almond trees. Wild barley and oats were rarely present, and they started to become more popular from 7,000 B.C. (Mesolithic). Thanks to the remains of animals' bones (also used to determine the three stages of this period), it has been possible to understand the kind of meat that the inhabitants of the cave used to eat. The majority of the remains were of wild horses and donkeys. There were also remains of deers, pigs, hares, turtles, and birds. The number of foxes, cattle, caprine animals, moles, and small fish was minor. The presence of small fish is proof of the fishing done close to the coast probably due to the lack of proper boats. In terms of tools, the archaeologists have found mainly flints and some instruments made of obsidian from the island of Melos. There is no sign of ceramic, burials, and architectonic structures in that period (Stiner and Munro 2011).

During the Mesolithic (8,300–6,000 B.C.), the cave of Franchthi continued to be accessed after a stage in which it was abandoned due to climatic changes. We can distinguish two settlement phases. In the first phase, the same plants of the Upper Paleolithic were cultivated with a few exceptions: oat and barley became common

while we do not have the Boraginaceae anymore, and peas and pears made their appearance. This data are probably the result of an environmental change. As for hunting, the equine and caprine species has been replaced mainly by deers. It seems that the inhabitants of the cave had developed better fishing skills since there are more remains of marine fauna and sea urchins. This shows a change in the habits and preferences of the inhabitants of the cave (Farrand 2003).

The second phase of the Mesolithic is characterized by a relevant increase in fish remains, fish of larger size in particular. This indicates that the inhabitants of the cave could fish in deeper waters. Besides that there is also an increase in the presence of obsidian from the island of Melos. Since the island was located 150 km from the shore, we can conclude that the navigation techniques were also more advanced at this stage. The quality of stone tools had also improved. In this period, there is no sign of ceramics or architectural structures but we have the first burials. The most ancient tomb dates back to the Lower Mesolithic. It is the burial of a 25-year-old male in a contracted position and with no furniture. He died because of a wound on the forehead, and it seems that the man was not in good health probably due to malaria. Further studies conducted on the human remains in 1989 have shown that this burial is located in the higher strata of this period and that there are other burials underneath. There are at least five inhumations and two cremations. Human remains belonging to other people (two to five people) does not seem to belong to those burials. On the basis of these elements, we can conclude that probably the inhabitants of the cave had become sedentary (see Perles 2003).

At the beginning of the Lower Neolithic (6,000–5,000 B.C.), we can record several changes. First of all, the domestication of sheep and goats and the cultivation of wheat, barley, and lentils. In the same way, the production of utensils and polished stone, agricultural tools in particular, improved.

Another important change is the presence of ceramic production and the remains of architectonical structures (temporary dry-stone walls) that were found out of the cave, on the coast.

The ceramics are mainly dark monochrome pottery cooked at quite low temperatures (less than 650 ° C).

These innovations as well the presence of several other burials confirm the sedentary characteristics of the people who were staying at Franchthi in this period.

In the Medium Neolithic (5,000–4,500 B.C.), ceramics and the kind of animals' bones differ from the previous period. Most of the bones found mainly belong to caprine-ovine species and fish while we have fewer remains of deers, pigs, and cows. The ceramics are now of better quality with a cooking temperature that has raised 800 ° C ca. Obsidian is the most utilized stone in the lithic industry. Among the burials, we can highlight those of two females aged around 33 and 40, both of them have a furniture with some obsidian lamellae.

The Upper Neolithic (4,500–4,000 B.C.) is a continuum of the previous stage. The making of ceramics continues to develop. The number of animal bones coming from caprine and ovine species increases until they become the only kind of meat eaten with a minimum presence of cows, deers, and fish. Obsidian is used to make arrow heads and its presence is more and more relevant.

The Final Neolithic (4,000–3,000 B.C.) represents the last settlement phase at Franchthi's cave. Many scholars consider the Final Neolithic at Franchthi as a continuation of the Upper Neolithic. In fact, the further improvement in the making of ceramics has been the main development; at this stage, the ceramics are decorated. Obsidian is almost the only kind of stone used. The burials continue and infant tombs start to appear (see Hansen 1991).

The site was abandoned around 3,000 B.C., probably due to a sudden sea level rise that must have partially flooded the spaces used by the community. Sporadic finds of archaic period are evidence of the use of the cave as a rural cult site. These deposits have not damaged the prehistorical ones (Figs. 1 and 2).

Frankel, David

Jennifer M. Webb
School of Humanities and Social Sciences, La Trobe University, Melbourne, VIC, Australia

Basic Biographical Information

David Frankel is an Australian archaeologist with expertise in the prehistory of Australia, New Guinea, and Cyprus (Fig. 1). He was born in Johannesburg in 1946 and moved to Australia in 1963. He received his BA (1970) and MA (1973) in archaeology from Sydney University and his PhD from Gothenburg University, Sweden, in 1975. From 1975 to 1978, he worked in the Department of Western Asiatic Antiquities at the British Museum, before taking a lectureship at La Trobe University in Melbourne in 1978. He was appointed senior lecturer in the Department of Archaeology in 1982, reader in 1992, and professor in 2009. He retired in 2013 and was appointed emeritus professor.

As a student Professor Frankel worked at Burrill Lake, Irrawang, and Elizabeth Farm in New South Wales and at Kauri Point in New Zealand, Zagora in Greece, as well as in Israel and Cyprus, before embarking on his own career as a field director. His dissertation was a groundbreaking analytical survey of the White Painted ware pottery of Middle Bronze Age Cyprus. Published in 1974, it was one of the first studies to use multivariate statistical analysis of design motifs to assess social relationships.

Professor Frankel has served on numerous national bodies, including the Australian Archaeological Association, the Australian Quaternary Association, and the Australian Association of Consulting Archaeologists, and played a key advisory role in the development of indigenous cultural heritage and teaching programs. In 2012 he initiated an annual colloquium on Victorian archaeology and heritage management. He has also had an active engagement with the Jewish Museum of Australia, coordinating an exhibition on the Archaeology of Ancient Israel in 1986 and teaching adult education courses.

Frankel, David, Fig. 1 David Frankel with Early Bronze Age pottery from Cyprus, Larnaca Museum, Cyprus

Major Accomplishments

David Frankel has set new standards for teaching, research, and publication in Australia and beyond. His fieldwork has provided opportunities for training for generations of students while also serving as the basis for a teaching program strongly informed by the research process. His status within the discipline rests on an integration of the practical and theoretical aspects of archaeological research and a deep engagement with primary evidence.

In his early years at La Trobe University, Frankel developed innovative courses on the archaeology of Australia and Melanesia and began an active program of fieldwork in order to develop a research profile for the discipline and cater to the needs of students. Over the next decade, he carried out excavations at Sunbury, Moonlight Head, and Phillip Island in Victoria, Barham in New South Wales, and Karremarter and Koongine caves in South Australia, as well as in the Gulf Province, Papua New Guinea. He developed new models for assessing changes in land use, technology, and behavior during the last 10,000 years. *Remains to be Seen: Archaeological Insights into Australian Prehistory*, a textbook published in 1991, drew heavily on these studies and on his courses in Australian archaeology (Frankel 1991). It differs from other texts in its self-conscious evaluation of the research process and is used extensively at Australian universities.

In the 1990s Frankel turned his research focus to Cypriot prehistory. A decade of excavations at the prehistoric Bronze Age settlement of Marki uncovered deposits spanning 500 years in the largest exposure of any settlement of this period on the island (Frankel and Webb 2006). This was followed by the excavation of Bronze Age cemeteries at Deneia and a Chalcolithic hunting station at Politiko and the publication of Early and Middle Bronze Age cemeteries at Psematismenos and Karmi and a mining and pottery manufacturing site at Ambelikou (Frankel and Webb 2007, Georgiou et al. 2011, Webb and Frankel 2013). These projects have had a profound influence on the understanding of prehistoric society in Cyprus and led to new insights into issues of households, identity, ethnicity and migration, technology transfer, population growth, and social relationships. Importantly, Frankel's excavation reports offer a new approach to presenting the archaeological record and use innovative technologies to make large quantities of primary data available in digital form. In recent years Frankel has returned to Australian prehistory, with the publication in 2017 of a general book on the Aboriginal archaeology of southeastern Australia (Frankel 2017. See also Bird and Frankel 2005).

Professor Frankel has played an important role in shaping research policy in Australia as a member of the Australian Research Council's Research Evaluation Committee, Excellence of Research in Australia (2010, 2012), and Humanities Disciplinary Panel (1996–1998). His 1998 review of archaeology in Australia for the Academy of Humanities made a major impact nationally. He is a Fellow of the Australian Academy of the Humanities; a Fellow of the Society of Antiquaries, London; and the recipient of a Prime Minister's Centenary Award for services to Australian society and the humanities. In 2016 he was awarded the Rhys Jones Medal for Outstanding Contribution to Australian Archaeology by the Australian Archaeological Association. He is a member of the Australian Institute of Aboriginal and Torres Strait Islander Studies and joint editor-in-chief of the Swedish monograph series *Studies in Mediterranean Archaeology* and has served on the editorial boards of *Archaeology in Oceania*, *Journal of Australian Studies*, and *Mediterranean Archaeology*.

French Guiana: Archaeology and Indigenous Peoples

Gérald Migeon
SRA Guyane (Ministère de la Culture), Cayenne, France

French Guiana, a country of 84,000 km^2, was inhabited by approximately 50,000–100,000 Amerindians before the European conquest; in the late seventeenth and early nineteenth century, the Amerindians were reduced to less than a thousand throughout the whole territory (as a result of bacteria shock, wars, escapes, etc.).

At the end of the nineteenth century, during several world's fairs, the Kali'nas were displayed in human zoos.

In 1930, the territory of Inini was created, to "protect Indians from civilization."

Between 1946 and 1969 (which marks the end of the status as a territory for the Inini), some geographers (Hurault, Frenay) and ethnologists (Grenand Pierre and Françoise) mingled with the people from "the Hinterland."

In 1970, a prefectorial decree limited access to the south of French Guiana, still in order to protect the "primitive and traditional populations who live of the forest. . .." Young Amerindians, however, were sent to religious homes, to be "educated."

French Guiana today counts six Amerindian nations and four different groups of Bushinengés (Some terms like "noir-marrons" have special historical/cultural significance in this context – don't know how to translate them. It refers to a cultural group of mixed racial heritage. I simply use the term "Maroons" like Richard Price does) (Maroons or descendents of runaway slaves) who are all regarded as indigenous, plus Metropolitans (people from the European French territory), various Creole communities (French Guianese, Saint Lucian, Martiniquan, Haitian, etc.) as well as more recent arrivals including Chinese, Lebanese, Hmong, Peruvian, Colombian, and other immigrants, making it an ethnically diverse and multicultural country.

Administratively speaking, French Guiana is 1 of the 100 departments of France, that old Jacobin country, which is made up of 1 single people, the French people. French Guiana is still, to this day, "an administrative department like any other," even though, in 2014, this overseas department is to become an overseas collectivity (perhaps similar to the New Caledonian model) within the legal framework of decentralization. French Guiana, however, is the only French department in which an "indigenous" group lives, according to the international definition.

France has not officially recognized Amerindian and Bushinengés peoples of French Guiana, neither through its national laws nor through many international treaties or conventions. For example, it has neither ratified the Convention 169 of the ILO (Article 13 de la Convention 169 de l'Organisation Internationale du Travail (O.I.T): "*[. . .] les gouvernements doivent respecter l'importance spéciale que revêt pour la culture et les valeurs spirituelles des peuples intéressés la relation qu'ils entretiennent avec les terres ou territoires, ou avec les deux selon le cas, qu'ils occupent ou utilisent d'une autre manière, et en particulier des aspects collectifs de cette relation.*") nor the UN Declaration on regional languages, nor the Declaration on the Rights of Indigenous Peoples, adopted on September 13, 2007, at the UN (**Article 11 (extraits) de la** Déclaration sur les droits des peuples autochtones: "*1. Les peuples autochtones ont le droit d'observer et de revivifier leurs traditions culturelles et leurs coutumes. Ils*

ont notamment le droit de conserver, de protéger et de développer les manifestations passées, présentes et futures de leur culture, telles que les sites archéologiques et historiques, l'artisanat, les dessins et modèles, les rites, les techniques, les arts visuels et du spectacle et la littérature.").

In this short presentation on the relationship between archaeology and indigenous peoples in French Guiana, the current legal situation will be presented first, followed by the relationship to the Earth and sites; objects and museums will be the concern of the third section, and finally, the multicultural approach gradually being set up in French Guiana will be presented as a tentative conclusion of our thinking on this subject.

Current Legal Situation and the Struggles of Amerindian Demands

Some decrees have superficially masked the monolithic French republican law. Since 1970, some French laws are applied "notwithstanding": limited access to the southern zone, non-conscription of indigenous boys, the collective use rights of state land (1987), etc.. It is clear that French Guiana is not quite the old Gallic country (metropolitan France).

A 1970 prefectural decree restricted access to certain parts of French Guiana to protect indigenous peoples from the evils of civilization. It was followed by the land decrees of 1987 and 1992 establishing articles R.170–56 and R.170–58 of the Code of State Domain. The Ministerial Decree of 14 April 1987 (art. 170.56) allows "The people who traditionally draw their livelihood from the forest" (Amerindians and Maroons or Bushinengés) to be granted "on federal lands in Guyana collective use rights for hunting, fishing and, in general, for any activity necessary for the subsistence of these communities."

This concerns only use rights; the ruling n·98-777 clearly reaffirms that the State private domain can only be granted to the benefit of people, not of communities.

Since 1981, with the creation of the Association des Amérindiens de Guyane française (which includes the six Indian nations), and after Félix Tiouka's address to the French State in 1984 and the advent of the Fédération des Organisations amérindiennes de Guyane (1992), the struggle of native Americans (conducted mainly by the Kali'nas) intensified: demands for access to their native language, their culture, their own political organization, some land, etc.

Membership to the COICA (Coordinadora de las Organizaciones Indígenas of the Amazon Basin) in 1992, as well as participation in the Charter of the Indigenous and Tribal Peoples of the Tropical Forests (Penang, Malaysia), also strengthened the internationalization of the struggle for Amerindian pride and recognition of the rights of indigenous peoples.

The creation of the Guiana Amazonian Park (le *Parc amazonien de Guyane*) in February 2007 may be an opportunity or a disaster for the Amerindians of the forest. It is too early to make a judgment!

In 2008, the "Conseil consultatif des peuples autochtones de Guyane" was created, but to this day they have not yet held a meeting.

The Relationship to the Earth and Archaeological Sites

The relationship to the Earth allows, in many societies, especially in pre-industrial societies, the construction of territorial identities as well as individual and collective local roots, based on the past, memory, and heritage. Archaeological sites, by their very nature, are part of the Earth, of Mother Earth, of the Earth as a food resource, for indigenous peoples.

Inselbergs, the shelters under rocks and caves, which are inlets into the Earth, and also rock art sites, are seen as sacred.

Like almost everywhere in the world, Guyanese archaeological sites, including Amerindian sites (*We only speak very rarely about Bushinengés archaeological sites because their authentication is not yet as developed; the age of these peoples in Guyana has not yet produced archaeological sites in the usual sense. We will return to it later.*), are under threat of being destroyed by the natural processes of erosion and on a larger scale by recent "economic and social development," characteristically the construction of roads, subdivisions, schools, hospitals, etc. and heavy extractive

activities, such as sand, granite, and laterite quarries, and both illegal and legal gold mines.

But the main problem remains that of the territories claimed by some Amerindians. The French government does not recognize collective land ownership by a community, nor does the administration of the Guiana Amazonian Park created in 2007. Only those areas used by populations who "*traditionally draw their livelihood from the forest*" are recognized.

In recent years the archaeology department of French Guiana has drawn inspiration from the principles held by Canadian archaeologists, in particular that of "recognition and respect for the spiritual bond that exists between Aboriginal peoples and special places and features of the landscape of high symbolic significance" (Canadian Archaeology Association, Statement of Principles for Ethical Conduct Pertaining to Aboriginal (www.canadianarchaeology.com/caa/fr/enonce-de-principes-dethique-touchant-les-autochtones)).

Thus, the altars of the ancestors, the altars of the dead, traditional and illegal cemeteries, and sacred Bushinengés groves of Apatou and of Papaïchton are protected, as are the sub-contemporary and nonofficial Amerindian cemeteries in Kali'nas villages on the west coast of French Guiana, by being integrated to the database Patriarche, as sites on the national archaeological map.

In addition, during each preventive or programmed study, Amerindian communities living on or near the archaeological sites concerned are not only informed of the arrival of archaeologists, but field work (prospecting, testing, excavating) does not begin until permission to do so is granted by traditional chiefs and shamans. This was the case in Kourou during excavations conducted prior to the construction of the *Soyuz Launch Complex*, which unearthed graves, and also at Awala-Yalimapo during the excavations of funeral urns, in 2009, 2010, and 2011.

And what about objects and their exhibition in museums?

Objects and Museums

According to the French Heritage Code published in 2004, it is neither legal nor obligatory to return bones belonging to indigenous peoples, nor objects found in their graves, nor any other objects deemed "sacred" to them.

The cultural significance of human remains and associated objects for indigenous communities is such that we duly reinstated, in practice and in law, a temporary storage space held by the State, in the municipality of Awala-Yalimapo in 2010. Similarly, following a study, the associated Amerindian human remains and funerary urn were entrusted to the care of the customary chief of Awala-Yalimapo. French law allows this type of stocking, if the archaeological remains are preserved and kept safe (normally under the responsibility of a qualified heritage agent). For now, the remains of the urn unearthed in 1997 are well kept in a communal room, but will a subsequent reburial by the community take place? When this happens, should we consider then that their conservation can no longer be ensured? Only time will tell, but the chances lay in the future and the confidence we have in the Kali'na community.

Furthermore, in November 2011, the archaeology department was approached to mount an exhibition, with the loan of funerary urns excavated since 2009, to be held in the town's library in 2012. Both points of view, Amerindian and Western, will be presented in Kali'na and in French, on the functions, symbolism, representation, etc. of the objects presented to the population.

The practices of museums have also evolved; the Museum of Guyanese Cultures regularly mounts exhibitions of the peoples of Guyana, using bilingual or trilingual signage, where the participation of indigenous peoples is sought, active and valued.

The Multicultural Approach

In 2010 in Awala-Yalimapo, a township of 1500 inhabitants founded in 1989 at the request of representatives of the Kali'na from the township of Mana, the Amerindian Mayor created a Council of Culture. The Council brings together representatives of the town associations, of the Town Hall, as well as two traditional chiefs; one of the goals is to establish the identity of the

municipality and the community, based on the past as it is revealed, to a large extent, by archaeology. Discussions and briefings are organized several times a year, thus allowing people to get better acquainted and speak a shared language.

The results of archaeological studies are made available in a timely manner to the communities and citizens of French Guiana, but admittedly not always in a manner that is accessible to all. In addition, conceptual approaches are different: archaeologists are used to sorting, classifying, and dividing remains, while the Amerindians consider minerals, animals, plants, and their spirits and humans as an inseparable whole.

Since 2010, however, the Awala-Yalimapo town council has been even better at reclaiming ownership of its past. Thanks to regional, national, and European funding, it has implemented training for four young Kali'nas in order to carry out a participatory inventory, relying on the help of heritage professionals, with a view to better understand Amerindian heritage in the township and contribute to its future prominence by the community.

This inventory is based on traditional field surveys (archaeological surveys, architectural surveys, etc.), but also oral based, that enhance the knowledge and expertise of the elders. The participation of Amerindian youth in the knowledge of archaeological heritage is growing; and the recruitment of one or more young Kali'nas as archaeologists or heritage officers in the coming years should enhance the sharing of oral and written knowledge. Archaeology can also become a means of social development for members of indigenous communities.

The Kali'na township of Awala-Yalimapo thus plays a pioneering role in the conservation of its heritage, shared by other Amerindians of French Guiana, whom are less active for various reasons.

Camopi, another Amerindian (Teko and Wayãpi) township on the Oyapock river, also seeks to foster their own heritage, through basketry workshops led by elders, photographic exhibitions taken by young people in their villages, or archaeological objects collected by their own families and presented to all during Heritage Day in 2008.

Other communities, such as those of the Tekos (Arawaks) of Balate in Saint-Laurent-du-Maroni, or that of the Kali'nas of Yaou (Bellevue) in Iracoubo, not to mention the Wayana, whose one rite of passage, the Maraké, is in the process of being registered as immaterial heritage for humanity, have expressed great interest for the archaeological heritage of their respective traditional territories.

As for the Bushinengés, somewhat lacking in this presentation, they have not been forgotten, but their awareness of the importance of material heritage, particularly archaeological, is only recent. One of the first archaeological research programs on Maroon groups of Guyana is expected to begin in 2012.

Conclusion

The address to the French people and government of, issued by Félix Tiouka on December 9, 1984, has thus borne fruit, even though maturation has been long and painful.

Since 1981, the year in which the Association des Amérindiens de Guyane Française (currently called the Fédération des Organisations Amérindiennes de Guyane) was created, archaeological heritage has become a preoccupation for Amerindian nations and particularly that of their political and spiritual leaders, their traditional chiefs, of their elected representatives, who see it as a way to provide historical legitimacy that is sometimes contested by other communities living in Guyana but also as a way to reinstate their culture in the long time of history.

French Guiana: Archaeology and Minority Communities

Gérald Migeon
SRA Guyane (Ministère de la Culture), Cayenne, France

French Guiana, one of the overseas departments of the French Republic, is composed of various ethnic minorities who are administered from a cultural, political, and economic perspective at State, Regional, and Departmental levels which

are dominated by Metropolitans (French people from Metropolitan France), Guyanese Creoles, and people of Chinese and Lebanese descent.

These minorities include six American Indian nations and four Bushinengé groups, all of whom are considered native, diverse Creole communities (from Saint Lucia, Martinique, Haiti, etc.) and more recent immigrants such as the Hmong, Peruvians, Colombians, etc. that make up this multiethnic and multicultural country.

This schematic and quick presentation of the sociocultural groups in Guiana may appear simplistic and caricatural. In the following paper, we will attempt to show that this is unfortunately the case, especially concerning the position of the archaeological heritage of minorities in the institutions responsible for preserving cultural heritage (the archaeology service of the Ministry of Culture and local museums), even though recent understanding and awareness of this fact have led to some progress over the past 15 years.

Archaeological Sites of Minorities

The national archaeological map (Patriarch) does not allow for the easy integration of a number of places of worship and cemeteries dating from the eighteenth century which are still in use, such as habitat or cemeteries which are known only through oral tradition and for which physical evidence is tenuous, even impossible to find.

And yet, in French Guiana, the Amerindian, Bushinengé and Creole populations practice many rites in places considered natural by the Metropolitans and other communities living in Guiana. It is worth mentioning, for example, the ancient Amerindian cemeteries of Mana, Awala-Yalimapo, and Iracoubo, the sacred forest of the Bushinengé in Apatou, the old houses of traditional Aluku chiefs in Boniville or of the grand Man Difou in Papaïchton, the Haitian voodoo cults at the foot of trees in a number of places like the rock carvings in Rémire-Montjoly, the Calvary of Bourda in Cayenne, etc.

How then can one recognize an Amerindian or Bushinengé cemetery when there is nothing to signal the location of the graves, if only by trusting the local people?

How does one know that a particular part of the forest is sacred and that only those who are initiated can enter it?

How can one guess that the remains of a few bottles, planks of wood, and a destroyed cassava oven are sacred because they are those of the last Grand Man of the Boni of Papaïchton?

Finally, when, during surveys, for example, we identify a voodoo place of worship often made up only by offerings of food and flowers and candles that leave little trace for future archaeologists, are we to save it on the national database or not?

Technically and theoretically speaking, it is much easier to record Amerindian sites, such as polishing stones, petroglyphs, etc. which leave tangible traces, than Bushinengé habitats of the eighteenth and nineteenth centuries which are virtually invisible.

Much of the problem lies in the immateriality of many of the human activities practiced by these ancient civilizations which did not necessarily build monuments with stone or brick. This is especially true in a context where tropical plants offer a wide range of building materials as well as effective and simple tools to make. To cut, you take a piece of bamboo, to scrape, a shard of quartz lying on the ground, to serve food, a palm frond, etc.

In French Guiana, we have decided to include ancient and contemporary Amerindian and Bushinengé cemeteries as well as the altars and sacred groves of the Bushinengé, Aluku (one of the four Bushinengé groups or Maroons of French Guiana), and Creole habitats in our list of archaeological sites in order to protect them. The Creole village of Guisanbourg near Regina, for example, founded while slavery was still legal, has been abandoned by its inhabitants for nearly 30 years but is still regularly visited by former families each year in a "pilgrimage."

For now, it is not intended to "restore" these Bushinengé or Creole habitats and much less their burial sites as Bushinengé cemeteries are forbidden to the uninitiated that we are and even to some of the Bushinengé population.

However, an innovative project is presently being put in place, in association with the Saül city council and the Guyanese Amazonian Park (PAG), around the Agasso House, the name of an old Saint Lucia gold prospector and grocer from Saül. The house has been recovered by the municipality, who want to convert it, after undertaking a study and restoration-consolidation, into an eco-museum displaying the tradition and history of gold mining in the region.

There is also the issue of conservation of cultural landscapes, as in the case of hundreds of hectares of former Amerindian farmland or Bushinengé Kottika burnt brush piles (the latter being classified as natural sites) that have shaped original cultural landscapes and are therefore considered by the Archaeology Service of French Guiana as archaeological sites, since they were modeled by man.

In the first case, some field areas have been set aside as natural areas of ecological interest, flora, and fauna (ZNIEFF) with the support of government department of ecology. One might object that it is an error to include what is natural as cultural, but we say that it is better to protect twice rather than once! On the contrary, I believe that this offers complementary protection since both natural and cultural heritage are inseparable.

The Archaeological Collections of Minorities

The three "museums of France" have collections coming from different histories.

The oldest, the Musée départemental Franconie, which dates back to the early twentieth century, is at once an historical museum and display cabinet of curious exhibits. Naturalist collections and some objects from different indigenous and traditional peoples of French Guiana (Amerindians, Bushinengés, Creoles), together with an amazing collection of paintings and engravings by convicts, are exhibited there in a permanent collection.

The Museum of Guyanese Cultures, administered by the Region, holds a more varied collection and, more importantly, has been established since the late 1980s by an inspired curator. Exhibitions, which are only on temporary display, are often thematic, multicultural, and cross-disciplinary and aim to show Guyanese cultural diversity, even if the collections are mostly made up of Amerindian, Bushinengé, and Creole ethnological objects. The difficulty in French Guiana lies in the demarcation between the archaeological and the ethnological. Is a Kali'na vase from the 1930s considered ethnological or archaeological? And what about a Saramaka bench? And Creole furniture? It all depends on the method used: Was the object collected in its context? In this case, it is archaeological; or was it collected elsewhere, such as, for example, in an auction? In fact, it is better to understand the objects in their extended cultural and functional context, in a continuum rather than trying to catalog, classify, or put the objects and concepts away in a drawer.

The third museum is in fact an eco-museum established in 2008, which presents, in a beautiful Creole house, once the trading post and home of a prosperous family, collections relating to life on the Approuague River in the early and middle twentieth century and its industrial heritage. Indeed, the owner of the trading post also had a sawmill, located next to where the wood was worked prior to being exported. An historical introduction is given in several windows displaying pre-Columbian objects and others dating from the colonial period in a broad sense, which considers the development of lowlands, particularly through the reclamation of flooded land and the contribution of the first steam engines of the Industrial Revolution.

All three museums are housed in Creole mansions, should this signify something particular? Everyone is free to find the symbol hidden behind these beautiful wooden facades. But it is clear that the dominant Creole minority sought primarily to preserve its past more than the past of other communities in French Guiana.

What happens elsewhere in French Guiana in the noninstitutional places?

In another article in this Encyclopedia *Archaeology and Natives in French Guiana*, we

highlighted the pioneering role of the Kali'na community from Awala-Yalimapo, which took control over its heritage, conducting a participatory inventory, exhibiting past and present objects, and educating young people in research techniques, conservation, and heritage management.

We also need to mention the initiative of the Kourou association Kalawachi, who over 3 years have set up and organized an exhibition on Amerindian tradition, in a traditional kalian hut near Kourou.

Exhibitions of their own culture by young Hmong in Cocoa, the most populous Hmong village in Guiana, have emerged in recent years.

In contrast, the Chinese and the Lebanese have not demonstrated, to date and to our knowledge, any desire for heritage recognition.

As for the other groups in French Guiana, who were the earliest to arrive (and who still continue to arrive today) such as Haitians, people from Martinique, Indians from India, or those who arrived more recently such as Peruvians, Colombians, Guyanese, Surinamese, or Brazilians, they are hardly visible in official exhibitions. Even if behind a Palikur or a Wayãpi, one may find a Brazilian. Similarly some Saramaka or Djuka who reside in French Guiana may have a Surinamese passport.

Conclusion

To conclude, we would like to examine the representation of individuals originating from minorities in archaeological and heritage institutions.

Amerindian political and cultural struggles carried out mainly by the Kali'nas have intensified since 1981, with on the one hand the creation of the Association des Amérindiens de Guyane Française, which includes the six Indian nations, and on the other hand, after the French State Address by Felix Tiouka in 1984, with the advent of the Fédération des Organisations amérindiennes de Guyane in 1992.

The demands for access to their native language, culture, land, own political organization, etc. have led the Kali'nas of Awala'Yalimapo to take control of their culture and, in particular, their archaeological heritage. At a regional level, only Sandra Kayamaré, who was initially employed with the regional archaeology service on a fixed term contract, was later permanently hired by the National Institute of Preventive Archaeological Research (INRAP), though unfortunately not for the Carte archéologique nationale.

Currently two young Amerindians, Eleluwa Tiouka, who studied archaeology in Paris, and Anne-Marie Chambrier, who works occasionally with the archaeology service of French Guiana, have indicated their intention to work in this field.

In museums and other heritage institutions, representatives of minorities are rare, as the majority of positions are occupied by Creoles or Metropolitans. The weight of history still weighs very heavily in Guiana!

French, Charles A. I.

Manuel Arroyo-Kalin
Institute of Archaeology, University College London, London, UK

Basic Biographical Information

Pressed on the point, Charly French (Fig. 1), the Canadian-born UK-based Professor of Geoarchaeology at the University of Cambridge, recalls that he fell into his first excavation – a deep pit for plutonium rods at McMaster University – when he was four years of age. However, his steps into the field of geoarchaeology begin with his first archaeological foray: helping out with the excavations at Wharram Percy, Yorkshire, during a visit to the UK in 1971. This experience prompted him to return to Britain to study archaeology. During his bachelor's degree at the University of Wales, Cardiff, Charly was taken in by landscape analysis and wrote an undergraduate dissertation on the earlier prehistoric molluscs and paleo-vegetation of the dry valleys of South Wales (1975). Immediately after, Charly took up a job with Francis Pryor, digging and

French, Charles A. I., Fig. 1 Professor Charles French in the McBurney Geoarchaeology Laboratory. (Photo by Tonko Rajkovaca)

analyzing molluscs at Fengate. This he followed up with a cataloguing job at the Royal Ontario Museum, and, next, with excavations at East Karnak in Egypt. He then embarked on the study of a Masters in Environmental Archaeology under the direction of Professor Dimbleby at the Institute of Archaeology, London. Around the late 1970s and up to the mid-1980s, Charly was employed by Francis Pryor as part of the Welland Valley Project team and the Fenland Project, leading to the discovery of Flag Fen and the Etton causewayed enclosure. At the same time, he successfully obtained a Ph.D. at the Institute of Archaeology, London, in July 1983. His dissertation, which focused on fen-edge and river valley site/landscape data, was defended in June 1983, a month before receiving a deportation order for overstaying in the UK (successfully appealed with the support of Ian Longworth at the British Museum and Geoff Wainwright, then Chief Archaeologist of what would in time become English Heritage). At around this time, Charly got together with his partner Kasia Gdaniec, also an archaeologist, joined the UK Institute of Field Archaeologists and (with Francis Pryor and Maisie Taylor) formed the Fenland Archaeological Trust, which oversaw the opening of Flag Fen to the public a year later in 1986. Charly went on to work in contract and developer-funded archaeology in the later 1980s and early 1990s, until – unexpectedly, in April 1992 – he was made Lecturer in Archaeological Science at the Department of Archaeology, University of Cambridge. By this time, Charly was already one of the pioneers in the use of soil micromorphological analysis to tackle landscape and archaeological research questions. In 2000, Charly became head of the Department of Archaeology and Senior Lecturer in Archaeological Science. In 2005, Charly became Cambridge University's first Reader in Geoarchaeology. In 2009, he received the Pilkington Teaching Prize, and in 2012, he became the first Professor of Geoarchaeology at the University of Cambridge.

Major Accomplishments

As a researcher, Charly's main activities have centered on the application of geoarchaeological, especially micromorphological, analytical techniques to tackle archaeological questions. At Cambridge University, he oversaw the development of the McBurney Geoarchaeology Laboratory (Fig. 1), the world's largest archaeological soil micromorphology laboratory. The McBurney

Lab currently undertakes investigations and contract work funded by research bodies and developers (Charly acts as consultant and micromorphologist in many parts of Britain and beyond). The lab also serves as a hub for postgraduate research and undergraduate teaching and has its own in-house facility for the manufacture of archaeological thin sections.

Charly's approach to geoarchaeology is a unique blend between the study of specific features of anthropogenic deposits and the interpretation of signatures of geomorphic and paleopedological processes affecting the archaeological record. This perspective, which is firmly anchored in landscape evolution and landscape history, emphasizes the reconstruction of buried landscapes, the characterization of archaeological formation processes, and the study of landscape degradation and human impact. Recently, Charly has also turned his attention to the interpretation of domestic space within settlement sites. The multiple strands of his approach make up a vast bibliography (some case studies can be found in his book *Geoarchaeology in Action: Studies in Soil Micromorphology and Landscape Evolution* (French 2002)) and are also well represented by the research of his former students. The latter make up a cohort of world-class geoarchaeologists that use soil micromorphology in a wide range of landscapes across Europe, Africa, the Middle East, the Americas, Australia, and Asia. Many of them are now university lecturers and researchers in different institutions around the world.

Charly's regions and countries of special research interest have included the East Anglian fenlands and the river systems that drain into them, the chalk downlands of Wessex, the Channel Islands, northern Bosnia, northwestern India, southern Patagonia, and the Ica valley of southern Peru. He is currently involved with a number of research projects: multidisciplinary investigations of Neolithic/Bronze Age environmental change in the Avon River Basin around Durrington Walls and the Kennet valley around Avebury; geomorphological and micromorphological investigations of Holocene erosion and paleosol sequences in southern Sicily, the Sava River Basin of northern Bosnia, the island of Herm (Channel Islands), and coastal and steppe regions of southern Patagonia and Tierra del Fuego in Chile; and the geoarchaeology of the Ica valley in southern Peru, as well as more site-specific investigations of settlements of the Harappan period sites in Haryana and Rajasthan provinces of northern India. The McBurney Geoarchaeology Laboratory continues to attract research students from these regions and other parts of the world.

Freshwater Archaeology

Bradley A. Rodgers
Program in Maritime Studies, East Carolina University, Greenville, NC, USA

Introduction and Definition

Freshwater archaeology can be defined as archaeological research that takes place in or near streams, rivers, lakes, ponds, oxbow lakes, or inundated natural and man-made features such as springs, cenotes, or flooded mines and quarries. In this venue, freshwater archaeology will not include features located in oceanic sounds, bays, gulfs, and some seas that contain brackish (mixture of fresh and salt) water. For archaeological purposes, therefore, freshwater can be defined by water at which point the average salt content, or salinity, is or remains lower than .5 ppt (parts

per thousand). Typical oceanic salt content averages 35 ppt and importantly for archaeologists, 12 ppt is the point at which typical oceanic fouling assemblages such as corals, coralline algae, shellfish, and tubeworms as well as wood borers such as shipworms, piddocks, and gribbles can no longer live.

Freshwater systems typically demonstrate high levels of artifact preservation as well as a lack of concretion and biodegradation. The preservation qualities of freshwater are largely due to the absence of chloride ions, living corals, and fewer bio-organisms that break down artifacts. Preservation can also be enhanced by cold temperatures found in the deeper large bodies of freshwater exemplified by the North American Great Lakes. However, it should be noted that as sea levels rise, due to climate change, the defined geographical parameters of fresh- and saltwater systems, particularly riparian, will become more complex.

Historical Background and Key Issues

The chronological range of archaeological sites that may be located in freshwater systems theoretically stretch to the beginnings of mans' migration from Africa. Every stream, river, and lake crossed by early humans potentially contains invaluable artifacts or evidence of habitat sites and food-gathering activities. The Little Salt Spring site in Florida suggests that some prehistoric underwater archaeology is certainly possible and remarkable finds can be made. Archaic riparian fishing activity in the form of stone fish weirs has been noted in the American Midwest. And trading routes extending from the Caribbean to the Yellowstone region can be deduced by the presence of unique artifact materials of copper, mica, flint, and seashells found in excavations far from their origin, indicating that extensive freshwater-borne trade existed in North America as long ago as 2500 years before present.

Yet there are several major problems with exploring freshwater riparian systems for prehistoric archaeological evidence. The recent Pleistocene glacial period, which only ended some 10,000 years BP, has remade much of the geography of North America, Europe, and Asia, forming most of the northern river, lake, and gulf systems we see today. These recently formed river systems are extremely dynamic and tend to flood with some regularity, periodically scrambling or eliminating much of the evidence of human activity. In one recorded archaeological case study (albeit historical), a dozen archaeologically documented shipwrecks dating to the early nineteenth century were swept away in Eastern North Carolina during the flooding from hurricane Floyd in 1999. It follows that if this happens in historic times, then it must have happened in prehistoric times, creating similar problems for archaeological interpretation. Geologists relate that it is also not uncommon, given the proper circumstances of outlying severe climatic events, for rivers to dramatically change shape in very little time. Given a long enough time frame, river systems often form a braided system of older dried courses and oxbow lakes that can be located some distance from the present watercourse. It is easily demonstrated archaeologically that many nineteenth-century North American Western riverboats lie buried under cornfields or are entombed in the mud at the bottom of oxbow lakes. It must follow that in these instances, archaeological sites, be they prehistoric or historic, have not moved, the rivers have.

Yet freshwater historic archaeology has become a growing success story, in both rivers and lakes, with more scientific data accumulated annually. Most often these successful projects use research designs that tap into data presented by well-preserved sites that lie in more stable deep-water rivers and lakes in both Europe and North America. The more recent craft and vessels of the historic period lie in greater abundance on lake and river bottoms and can be used to piece together a patchwork quilt of archaeological information extending from Roman times to the twentieth century. As in all historic archaeological study, the goal is to gather information to better interpret the lives of the people who created these artifacts. Underwater archaeology is a new profession and not well represented in some major areas of the world. This entry will, therefore, concentrate solely and by necessity on the areas

of the world where most of the freshwater archaeology has taken place, Europe and North America.

International Perspectives

European Freshwater Archaeology

It would be impossible in this small venue to discuss all of the Continental freshwater archaeological finds. At best, some of the better examples can be described and placed in a sort of archaeological/historical context. As elsewhere, European lakes and rivers offer an archaeological glimpse into freshwater human activity. And as elsewhere, these studies are often enhanced by unsurpassed freshwater preservation of artifacts and strata. It should also be noted that the concept of freshwater archaeology adds an artificial barrier that does not concern most archaeologists, who most often follow overarching research designs regardless of what environment this information is located.

Likely the first freshwater archaeological research accomplished on the Continent of Europe centered on examination of Irish and Scottish Crannogs, small artificial islands that were built over and used as dwellings from the Neolithic period onward. Crannogs were placed deliberately in lakes, rivers, and estuaries as both a means of protection and to allow humans easy access to resource use and waterborne transportation. Proto-archaeological examinations of crannogs first took place toward the end of the nineteenth century but continue to present day, where modern scientific method and theory is used to glean a great deal of archaeological data concerning Neolithic and Bronze Age life.

Some of the earliest finds in the freshwater nautical archaeology venue are log boats discovered in Britain, Denmark, Spain, France, and Germany. The earliest of these seem to date from the Mesolithic period, examples being the Pesse, Netherlands, log boat (8300 BP) and a log boat site located in Locharbriggs, Dumfriesshire, in Britain (4000 BP). Log boat finds are common in the freshwater archaeological record, and their use spans virtually all recorded history until nearly present day. Log boats were produced in large numbers and despite river changes and flooding, many still exist in riverbanks and lake bottoms. Log boats were produced to carry out all activities associated with prehistoric and historic living practices including hunting, fishing, trading, exploration, and warfare. It can be surmised that log boats became more practical to human use after the glacial retreat and the growth of large Continental forests.

Woven or skin boats were likely used before this time. The Husan boat fragments (11,000 BP) seem to be the only archaeological evidence of these craft, but they are represented in the ethnographic use of woven coracles and hide kayaks. Sophisticated intermixing of log boat, skin boat, and woven boat technologies are also hinted at in the Evanshus, Berguter, and Karelia Petroglyphs. These early craft showed such utility that they are still being produced today in some areas of the world, but importantly in this case, and in the context of freshwater environments, these craft gave humans the ability to travel great distances, turning freshwater obstacles of lakes and rivers into freshwater roadways. Log boats, skin boats, and woven vessels allowed humans to migrate while taking better advantage of the environment for production of food.

European freshwater navigation technology changed during the late Neolithic and Bronze Age as humans found a greater need to take advantage of riparian, brackish, and estuarine environments to transport a new and growing wealth of agricultural commodities. Bronze and Iron Age flats were constructed combining log boat and skin boat technology as exemplified by the Brigg Raft in Yorkshire, England, and the Polish Galar flat (2800 BP). These early examples of flat boats designed for freshwater and estuarine trade began another vessel tradition that spans the entire historic range from that period nearly to present time. Flats, scows, ferries, barges, litter freshwater and estuarine environments, and rival log boats are the most plentiful example of freshwater vessel.

During this same period, vessels were produced in Europe to take advantage of both river and cross channel trade. These stitched plank boats were lighter and likely faster to paddle than log boats, and some were designed to not only navigate up rivers but to make short dashes

carrying tin between Britain and the Continent. Good archaeological examples of these types of vessels can be seen in the Dover Boat (3300 BP) found near the River Dour and the Ferriby Boats (3300 BP and 2400 BP) found on the Humber Estuary. From descriptions given by Sean McGrail and Basil Greenhill, these vessels can best be described as large canoe-type craft that could carry up to 7 t of material and driven by a fair-sized crew of paddlers.

The Continental freshwater archaeology trail continues in the rivers of Central Europe with Roman period riparian trade vessels of Celtic design referred to as the Laiback type, best exemplified by those archaeologically excavated and recovered at Pommeroeul. These river vessels were intended to be poled and later towed by animals on the peaceful Roman period rivers of Central Europe. They were plank built and could be quite large at up to 30 m in length. Their construction, with flat bottoms and slab sides, made them ideal for rolling cargo on and off from riverbanks, but unlike the other flats previously discussed, they were narrow enough to make headway towed against the river current. It can be seen in Roman funerary reliefs that another type of vessel shared the rivers of Central Europe with the Laiback type; the Blussus Boat is pictured as a large dugout-type vessel. It was designed to be towed upstream but oared downstream. As yet there are no archaeological examples.

It should be mentioned here that a fantastic discovery was made when the Italian Lake Nemi was drained in Northern Italy in 1929. Two vessels were discovered in the lake that dated to the reign of Emperor Caligula in the first century CE. The Lake Nemi vessels were flat bottomed and over 70 m in length, but otherwise built in the Romano-Greek oceanic vessel tradition. They were likely constructed as floating temples or palaces, and although they were destroyed by fire near the end of WWII, much of the stone and ceramic work for the deck buildings was saved.

The Scandinavian tradition in boat building and ship construction was only in its infancy during the Roman period. Many of these early vessels were intended to ply both fresh- and saltwater, but here, we will concentrate on those examples found in freshwater. Classic period Viking vessels were fully capable of transitioning from a marine environment to a riparian environment, but a full discussion of these seagoing vessels and their predecessors is not possible here. However, proto-Norse vessels such as the Als boat at Hjortspring in South Denmark is a good example of an early Norse-type freshwater technological tradition. It is dated to 2350 BP and described as a dugout-type boat with additional planks added, lapstrake style, to the sides. Adding to the proto-Norse style were a carved stem and stern. Als was found in a lake along with various weapons and likely placed there as a spoil of war. Als can be placed in context with other finds from Denmark; the Bjorke Boat (2100 BP) and the nineteenth-century finds of two vessels at Nydam (dated to 310–320 CE) together give a hint at how proto-Norse vessels evolved.

Finally it should be noted that many river and lake discoveries will not be mentioned here as they involve vessel types that were never intended for inland lake and river use. The Bremen Cog, located and excavated out of the River Weser, in Germany is a good example of an archaeological project that took place in freshwater, but whose implications mostly affect marine archaeology and seagoing technology. The Thames River alone contains many archaeological sites that may be termed freshwater but relate more to the sea. Blackfriars and County Hall sites represent a Gallo-Roman marine shipbuilding tradition that is beyond the scope of this submission. Other known historic vessel types such as medieval hulks and bardes will, no doubt, be discovered, perhaps well preserved in a freshwater environment. But these vessels are, as well, of a marine oceanic technical tradition and not intended to spend their working lives in freshwater.

North American Freshwater Archaeology

American freshwater archaeology is a recent phenomenon having been conducted to date with only one generation of trained archaeologists. But these archaeologists were trained to respond to the needs of their time. The period between the common use of scuba diving gear in the 1960s and the introduction of Federal and State cultural

resource management laws in the 1980s can best be described as a period of underwater cultural resource chaos. This time period leads to the destruction and near destruction of vast amounts of submerged archaeological evidence in often well-intentioned but ill-advised attempts to salvage and or recover freshwater shipwrecks of all types. This included the eventual complete destruction of the intact Great Lakes Schooner Alvin Clark (raised in 1969) and the near destruction of the Civil War ironclad gunboats USS Cairo (raised in 1964) on the Mississippi, along with Confederate ironclads CSS Neuse and CSS Jackson (CSS Muscogee), as well as a multitude of ship parts and machinery from other sites. It should be noted that although these Civil War ironclad gunboats were eventually saved, preserved, and curated, their complete destruction due to lack of preservation funding hung in the balance. Given this, a large amount of freshwater archaeological data has, since the 1980s, been retrieved in America's inland fresh waterways, and our understanding of maritime trade, ship construction, and history has been greatly enhanced.

In North America, freshwater archaeology can be divided between freshwater lakes and the great river systems that span the country. These freshwater systems were often commercially interconnected yet were serviced by unique freshwater technologies and ship classes that evolved to service an area's individual geographic needs. It is, therefore, most meaningful to organize this entry into a section concerning the Great Lakes and juxtapose that discussion with a section concerning American River Transportation.

The Great Lakes

The Great Lakes of North America consist of five large interconnected lakes that contain 94,500 m^2 (244,754 sq. km) of inland freshwater sea. The combined lake shores stretch for thousands of miles forming a partial boundary between Canada and the United States. The Great Lakes combined create the world's largest freshwater body exceeding 1300 ft. (396 m) in depth in Lake Superior. The upper lakes of Huron, Michigan, and Erie are on average 570 ft. (174 m) above sea level, while Superior is elevated an additional 20 ft. (6.1 m). Lake Superior became economically connected to the other lakes in 1856 by the busiest lock system in the world at Sault Ste. Marie. The lower easternmost lake of Ontario is 245 ft. (75 m) above mean sea level. Ontario receives the runoff of the Western lakes over the great cataract of the Niagara Falls located in Western New York State. Navigation, however, is made continuous with the other lakes by the Welland Canal system in Canada that bypasses the falls. Since 1825, the Atlantic port of New York has been connected to the Great Lakes via the Hudson River and the Erie Canal, while today, larger vessels can navigate from the Atlantic Ocean into the Great Lakes via the St. Lawrence Seaway.

Professional freshwater archaeological studies began on the Great Lakes in 1985 in Wisconsin waters near Bayfield with the publication of the first of several reports put out by the Submerged Cultural Resources Unit of the National Park Service – the *Submerged Cultural Resources Site Report: Noquebay*, by Toni Carrell. In all, three reports emerged from these efforts outlining the condition and relevant histories of several shipwreck sites in Lake Superior. It should be noted that unlike European studies that tend to concentrate on prehistoric occupation and freshwater vessels, American studies have remained within the historic archaeological realm. Dugout canoes and prehistoric artifacts no doubt exist in the lakes' area but as yet have received little archaeological attention.

At nearly the same time, a branch of the Wisconsin State Historical Society (WSHS) became charged with examining and managing the shipwrecks located on the State's bottomlands in both Lake Superior and Lake Michigan. The first of these management efforts took place in 1985 with a collaborative study conducted by the WSHS and East Carolina University (ECU) on the Schooner Fleetwing site. This single wreck study was published by David Cooper in 1988, as *ECU Research Report #6 The 1986–1987 Archaeological Survey of the Schooner Fleetwing Site, 47DR 168, Garrett Bay, Wisconsin*. This began an ongoing 28-year collaboration between East Carolina University and the State of Wisconsin that has

produced to date 4 books, 14 Master's theses, and an additional 12 collaborative and independent reports that can be accessed through the Wisconsin Historical Society and ECU websites.

Since that time, additional collaborations have been forged between the aforementioned entities and the Federal NOAA Marine Sanctuary at Thunder Bay; the Michigan State Department of History, Arts, and Libraries; the Rodger's Street Museum; and the Wisconsin Maritime Museum. Other organizations conducting freshwater archaeology and collaborations on the lakes include Texas A&M University (TAMU), Parks Canada, Wisconsin Sea Grant, as well as private nonprofit groups such as Save Ontario's Shipwrecks, and the Great Lakes Historical Society.

Freshwater archaeological research on the Great Lakes began with site-specific projects aimed at recording individual shipwrecks. This research was often driven by cultural resource management needs to identify the extent of the submerged resources on state bottomlands. Additional efforts soon branched to include systematic remote sensing surveys such as those conducted by the SHSW.

Site surveys of shipwrecks combined with and underlined by sound background historical studies have given, since then, a more focused view of the maritime history and archaeology of the Great Lakes. These studies demonstrate that during the nineteenth century, freshwater vessels transitioned or technologically evolved from generic sailing craft, that would have been at home in any oceanic environment, to vessels that were specifically designed to meet the needs and varying niches of the economic and geographic restraints placed on them. History and archaeology have demonstrated that nineteenth-century freshwater ships diversified in design and evolved via the increasing influence of large shipping and railroad companies.

The following descriptions of nineteenth-century vessel types are placed here in the historic order that they appeared. It should be noted that not all of the archaeological evidence for these vessel classes can be cited in this venue. The sustained and systematic exploration of the following identified vessel types follows the basic research design set into motion in 1985. It should also be noted that site-specific research has evolved to now include more salient overarching questions of culture, economics, and human systems interaction.

The Millecoquins vessel is named for the stream in Michigan's Upper Peninsula where it was found. Likely a brig or topsail schooner, the wreck is located several hundred meters from Lake Michigan where it was likely blown in a gale. This small vessel exemplifies the generic trading ships of the early nineteenth century and is largely intact and still contains its cargo of salt fish in barrels within the hold. Its dimensions of 65 ft. (19.8 m) by 24 ft. (7.3 m) with a five-foot (1.5 m) draft would have allowed it to navigate the unimproved harbors and river mouths of the Great Lakes. It had no centerboard, a sailing improvement adapted from the coast in the late 1830s and 1840s. It also contained an American penny in the mast step dated to 1833. This owner/operated vessel likely traded with various fishing camps located along the lake shores.

By the mid-nineteenth century, sailing vessels on the lakes increased in size and carrying capacity very dramatically and also diversified in form and function. This was made possible by an increased use of iron in construction, improved harbor infrastructure, and the use of centerboards. The addition of an internal centerboard (originally located beside the keel keelson structure and eventually moved to actually penetrate through the center of the ship) allowed better use of the fore-and-aft schooner rig that became predominant in lakes sailing vessels. These freshwater schooners evolved to become various classes known as Canal Schooners, Lumber Schooners, and, largest of all, the Grain Schooner and Schooner Barge. Smaller flats were also schooner rigged to service unimproved shallow water ports; these were known as Scow Schooners. All of these vessel types have now been archaeologically documented in site-specific archaeological projects, in many instances demonstrating the sophisticated nature of the designs. But sail was not the only type of power in use on the Great Lakes.

The use of steam had a great influence on nineteenth-century freshwater inland navigation.

Each of the following steamship classes has also been archaeologically documented in site-specific projects. Since there are few if any remaining plans for these early ships, the archaeological data is sometimes the only way to tell these ship classes from one another when a new site is located.

The geography and natural resources of the Great Lakes area allowed steamship companies to operate early inefficient steamships at great profit. Several factors allowed steam to compete and even dominate sail on the lakes much sooner than it could in an oceanic environment. First, distances between ports, though it could be hundreds of miles, were considerably less than that on the ocean. In addition, the boilers had all of the freshwater they could consume without the need to worry about salt buildup, while fuel was found in the abundant forest reserves that crowded the shoreline. A variety of classes of steamer have been archaeologically studied on the Great Lakes and include large passenger paddle wheelers known simply as Steamers. These vessels specialized in passenger transportation between the 1820s and the Civil War and were responsible for much of the migration westward in the nineteenth century.

Steam Barges or Lumber Hookers originated in the late 1840s and quickly found a niche towing heavily laden lumber schooners in what became known as the consort system. The consort system speeded transportation of lumber from the great pineries of the American Midwest to the east via the lakes. The Steam Barge towed as many as seven lumber schooners in line astern, alleviating the need for each schooner to carry a full crew. A Steam Barge, as is seen archaeologically, is simply a schooner hull, sometimes complete with centerboard, into which a single cylinder direct-acting steam engine, propeller, and boiler were added. Outwardly early Schooner Barges were given a deckhouse aft but later sported houses both fore and aft much like their technical progeny the Bulk Carrier. Internally, however, they remained for all intents and purposes, a schooner with a steam engine.

As mentioned, Bulk Carriers evolved on the Great Lakes from Steam Barges, the first being produced in 1869. Unlike Steam Barges, however, bulk carriers grew to enormous size to carry all of their cargo internally. Steam and propeller driven, these vessels pioneered large open cargo holds to accommodate fast and easy loading of unpackaged bulk commodities such as grain, stone, coal, and ore. It is not uncommon for these wooden vessels to exceed 200 ft. (61 m) in length with a 50-ft (15.2 m) beam and a 24-ft (7.3 m) depth of hold. Internally they evolved a very sophisticated support structure unlike anything produced for any other type of wooden vessel. Bulk Carriers are still in use today and when they transitioned to much stronger iron and steel hulls at the turn of the twentieth century, they became truly enormous; today some exceed 1000 ft. (305 m) in length.

One more lakes vessel class has been identified archaeologically and deserves short mention here, the Propeller or Passenger/Freight Propeller. These were fast, well-appointed medium-sized ships of less than 200 ft. (61 m) and a high length to beam ratio. Their purpose in the 2nd half of the nineteenth century was to extend passenger and manufactured freight rail service to the harbors and ports on the lakes that did not yet have rail.

North American River System

As happened in the Great Lakes, the period before adequate cultural resource management practice in the 1960s and 1970s opened a Pandora's box of sporadic riverboat recoveries in the American West. Riverboats Bertrand (1865) and Arabia (1856) were excavated on land (as the river had moved since their sinking), and partially recovered. The material remains of these vessels have made for spectacular historical museum exhibits by the organizations that recovered them, but unfortunately, much of the archaeological information concerning the construction and engineering of these vessels has been lost in their excavation. Many other sites were partially salvaged for their artifacts, engines, and boilers. But these sites do highlight the fact that rivers offer a unique opportunity for archaeological study. The preservation qualities of freshwater are well documented, and if the site can be placed in a holistic context, archaeologists are often offered

a greater potential to study the integrated maritime cultural landscape as it extends from the shoreline.

Sites included in this genre of research include abandoned and wrecked vessels, plantation landings, town waterfronts and submerged infrastructure, wharf and dock structures (some of which include abandoned vessels), bridge structures, and nearshore settlements and trading posts. Each of these types of study offers unique insight to human habitation. Yet it should be noted that although archaeological studies have taken place on all of these types of sites, they have not received the same professionally planned systematic research attention that the Great Lakes has received.

Riparian archaeological attention first centered on a wrecked steamboat with George Bass's 1980 survey of the Steamboat Black Cloud in the Trinity River in Texas. At nearly the same time, Gordon Watts conducted a visual and remote sensing survey of an area near historic Fort Fisher also in 1980 and followed this with an abandoned ferryboat survey in the N.E. Cape Fear River in North Carolina in 1986. These surveys contributed to the research design for the Yorktown Shipwreck Archaeological Study of an abandoned British seagoing collier of the Revolutionary period in the brackish water of the York River in Yorktown, Virginia. The project, under direction of John Broadwater, was conducted within a steel cofferdam between 1983 and 1994. Although the cofferdam made it possible to deal with the low visibility and currents of the river, it proved too expensive for routine river archaeology.

During this early period, scattered systematic remote sensing river surveys followed in the Delaware River near Philadelphia and White Oak River in Southeast North Carolina. Many abandoned and wrecked vessels were located in these surveys ranging from iron- and steel-hulled oceangoing ships of the late nineteenth centuries to canoes, johnboats, and flats from much earlier periods. In fact, the diversified nature of riparian submerged cultural resources and the difficulties involved in working black and brown water river sites tended to slow the development of a riparian archaeological tool kit. Archaeologists needed techniques to help them deal with lack of visibility, fast currents, and the location of sites that sometimes were not only submerged but also lay under several meters of flowing and viscous silt.

The study and excavation of the Maple Leaf site in the St. Johns River in N.E. Florida near Jacksonville between 1992 and 1994 became a test platform for riparian excavation techniques in the USA. The Maple Leaf project was a collaborative effort between the private nonprofit St. Johns Archaeological Expeditions and East Carolina University. During this project, Rodgers and Cantelas designed a portable prefabricated underwater cofferdam system that could be assembled in place on the wreck site. It was used in conjunction with surface-supplied air and underwater communications gear to excavate the vessel under 20 ft. (6.1 m) of black water (rich in tannins) and 8–10 ft. (2.4–3.0 m) of silt. The techniques, which included carrying clear plastic bags of water in order to see gauges, slate drawings, and tape measures, proved workable, successful, and inexpensive but required skilled technicians and many hours of labor.

Riparian archaeology continued with the examination of a ship's graveyard at Castle Island in the Tar/Pamlico River near Washington, North Carolina, between 1998 and 2002. Over a dozen southeastern river and estuarine working craft from sailing canoes to sharpies, oyster boats, and schooners dating from the early nineteenth century were recorded archaeologically. This collection included one unique style flat-bottomed, sloped-sided stern-wheeled river steamer later identified as an up riverboat. Another example of this class of craft was recorded in the Tar River near Old Sparta, North Carolina, between 2008 and 2010.

Although most of the freshwater river archaeology conducted in the United States has taken place in the Southeast, sporadic finds and work in Western Rivers are continuing, and finds continue to this day. Wreck sites on the Red River and the Missouri River have revealed an early low-pressure side-wheeler (TAMU) as well as the Montana (1879), the largest Mountain Steamer ever constructed and documented by ECU in 2003. Very recent finds have drawn the attention

of archaeologists to steamboat remains on the banks of the Yukon River. As can be seen, although conditions can be challenging, freshwater archaeology continues in the United States and other places around the world.

From Sautuola to Cartailhac

Ewa Dutkiewicz
Museum für Vor- und Frühgeschichte, Staatliche Museen zu Berlin – Stiftung Preußischer Kulturbesitz, Berlin, Germany

Introduction

"Papá, bueyes!" – This exclamation of María Sanz de Sautuola (1870–1946) gave way to a discovery that changed the view of the Paleolithic as much as it rarely happens in the history of science (Fig. 1 (left)). Around 1868, Modesto Cubillas Pérez (1820–1881) discovered the cave of Altamira and later informed Don Marcelino Sanz de Sautuola (1831–1888) of his discovery. Sautuola was a graduate jurist and was academically educated (Fig. 1 (right)). He was particularly interested in regional history and natural sciences. He introduced the cultivated eucalyptus tree to Cantabria, and for many years he was Vice-Chairman of the Provincial Monuments Committee. He collected antiques, fossils, and minerals (Sanz de Sautuola et al. 2004). After having heard about the discovery, he was particularly interested in investigating the cave. The estate of Altamira, which means "High View" in Spanish, extends over slightly sloping high-altitude meadowland about 4 km from the northern Spanish coast, near Santillana del Mar in Cantabria, about 30 km west of Santander. Under the estate, an underground system of caverns and narrow corridors winds through the limestone rock.

Sautuola began the first investigations of the cave in 1875. He concentrated his work on the floor of the cave and found some bones and stone tools. In 1878 he visited the Paris World Fair and saw the Anthropological pavilion where prehistoric artifacts from various excavations in France were exhibited. During this occasion, he spoke to the French prehistorian Édouard Piette (1827–1906) who gave him advice on what he should pay attention to while investigating the cave. Inspired by this conversation, Sautuola reentered the cave and examined it more thoroughly. He discovered that the entrance led to several galleries with different lateral branches. Farther back, these galleries tapered to a long, narrow, winding corridor about 50 m long, so that the entire cave system reached a total length of about 300 m (Sanz de Sautuola et al. 2004).

One day in 1879, when he took his 9-year-old daughter María with him, she went to a low cave hall, which her father had examined before. The father had to crawl on all fours and concentrated his work on the floor, but the child could stand upright. When she looked up, on the ceiling she recognized colorful paintings that her father had not noticed before. The red-brown figures of nearly two dozen bison huddled in the flickering lamplight (Figs. 3 and 5).

Definition

The discovery of the cave of Altamira marks a crucial step in the exploration of the Paleolithic. It opened our eyes to an important genre of human cultural achievements in prehistory. Rock art is not only a vast field of exploration today, but it is

From Sautuola to Cartailhac, Fig. 1 Maria (left) and Don Marcelino Sanz de Sautuola (right)

also evidence of a cultural practice by many prehistoric and modern peoples of the earth. Rock art, or parietal art, is a generic term for a number of art expressions, which share the fact that they are attached to natural rock walls. These can be rock walls in open terrain, in rock shelters, or in deep caves. Different techniques can create the images: painting, airbrushing, drawing, engraving, carving, or "finger-fluting." In most cases, a mixture of different techniques is applied. In Paleolithic rock art, often the natural form of the rock is used to give volume to the depictions and create three-dimensional impression. Thematically, mostly animals and humans appear. A large part consists also of negative and positive hand imprints. Geometric signs are abundant and accompany the figurative depictions. Concerning the motivation for creating rock art, different theories exist. They range from magical/ritual practices, initiation rites, and shamanistic practices of individuals and during group gatherings, as means for the expression of group affiliation, manifestations of history and mythology, landmarks, to large symbolical communications systems.

Historical Background

Archaeology was still a young science in the nineteenth century. After archaeological and various other "exotic" remains were collected for curiosity cabinets of European courts, the authorities established the first museums. The curators of these institutions were facing the problem of bringing order into the hundreds and thousands of objects. The Danish archaeologist Christian Jürgensen Thomsen (1788–1865) sorted the collections in his care according to their material and developed the so-called three-age system of Stone Age, Bronze Age, and Iron Age, which is still valid today. In the early 1830s, the geologist Charles Lyell (1797–1875) developed the stratigraphical method for determining relative chronologies for geological deposits (Lyell 1830). In 1838, Jacques Boucher de Crèvecoeur de Perthes (1788–1868) carried out the first systematic excavations in the Somme Valley (France). From 1847 on, he applied the stratigraphical method for determining the relative chronology of his finds and stated that man-made artifacts in association with animal remains in old geological layers prove that human existence reaches far beyond the biblical timespan (Boucher de Perthes 1847–1864). Although his observations and results were strongly criticized, more and more scholars and clergymen became interested in the study of caves, rock shelters, and open-air sites. In 1860, after having excavated the cave of Aurignac, Édouard Armand Lartet (1801–1871) proposed a first chronological subdivision of the

Paleolithic based on different *Leitfossilien* he found in his excavations (Lartet 1861). In 1865, John Lubbock, 1st Baron of Avebury (1834–1913), divided the Stone Age into the period of the knapped stone, "the Paleolithic," and the period of the polished stone, "the Neolithic" (Lubbock 1865). Later, it was Gabriel de Mortillet (1821–1898) who established the subdivision and succession of different Paleolithic periods (de Mortillet 1883).

With Charles Darwin's (1809–1882) publication *On the Origin of Species by Means of Natural Selection, Or, The Preservation of Favored Races in the Struggle for Life* (Darwin 1859), the world was shaken. For the first time, the biblical view (according to which God created the earth and all living beings immutably and assigned their place in the world a few thousand years ago with (Western) Man at the top) was called into question. In *The Origin of Species*, Darwin hints to the possibility that humans are the result of evolution in the sentence: "Light will be thrown on the origin of man and his history" (Darwin 1859, 424). Evolution of animals was a revolutionary thought; the evolution of humans was blasphemy. The phylogenetic proximity of humans and primates was expressed in detail by Thomas Henry Huxley (1825–1895) in *Evidence as to Man's Place in Nature* (Huxley 1863) and later in Darwin's *The Descent of Man, and Selection in Relation to Sex* (Darwin 1871). Here, Darwin refers to the archaeological investigations of Boucher de Perthes (1847–1864), Charles Lyell (1863), and John Lubbock (1865), and compares "civilized races," thus Western societies, with "savages," and classifies the latter as lesser developed.

Fossil humans were discovered long before Darwin's publication, but remained unnoticed by science. One particular find, however, stimulated minds. As early as 1856, 3 years before the publication of *The Origin of Species*, workers in limestone quarries found bones in the so-called Kleine Feldhofer Grotte in the Neander Valley near Mettmann (North Rhine-Westphalia, Germany), which they first thought were the remains of a bear. The remains were given to a local teacher and naturalist Johann Carl Fuhlrott (1803–1877). Already after initial investigations, Fuhlrott stated that these must be the bones of an ancient human form. In 1857 the anatomist Hermann Schaaffhausen (1816–1893) from Bonn examined the bones and came to the same conclusion (Schaaffhausen 1858). The bones were presented to the scientific community, but there were strong doubts about the age of this skeleton. One of the most important opponents was the anatomist Rudolf Virchow (1821–1902) from Berlin, who in 1872 completely denied that the find was an ancient human and stated that the particularities of the bones and the cranium were caused by pathological conditions. Until his death, he did not accept that the bones from the Neander Valley and other finds belonged to a primitive human form. Virchow was a strong opponent of the theory of evolution, which was not compatible with his social-liberal convictions. In the coming years, Fuhlrott and Schaaffhausen had to deal with strong hostility from scholars. It was thanks to the investigations of Huxley (1863) and Lyell (1863) that this find further received scientific attention.

The question of the age of human bones and artifacts, and whether humans had lived with extinct – so-called antediluvial – animals such as mammoths occupied the mind of the scientific world in the 1860s. It was Édouard Lartet who discussed this question in detail in 1861 in his publication *Nouvelles recherches sur la coexistence de l'homme et des grands mammifères fossiles réputés caractéristiques de la dernière période géologique* (Lartet 1861). A spectacular find from 1864 confirmed this assumption with convincing force: in the French site La Madeleine, the fragment of a tusk with a detailed engraving of a mammoth was discovered. This object, together with other examples of mammoths represented in mobile art like from Laugerie-Basse or Bruniquel, undoubtedly proved that the artists must have seen these animals during their lifetime (Lartet 1865). Despite some scientific resistance, the exhibition of these pieces at the Paris World Fair in 1867 led to the general acceptance of the simultaneity of humans and extinct animals, and the recognition of works of art from the so-called *l'époche du renne* (Lartet 1861).

These and many other milestones in the early history of prehistoric research led to a

confrontation with the prevailing biblical view on the genesis of humans. The possibility of human evolution challenged self-understanding in the Western world. This caused many controversies and oscillations between modernism and evidence-based science but also conservatism and rejection or even ridicule of new insights. In addition, Western scholars had a feeling of superiority toward other allegedly less developed peoples. On one hand, colonialism stimulated confrontation with other cultures, raised curiosity, but always in the context of the inferiority of the "less" developed culture. On the other hand, archaeological research led to more and more knowledge about Europe's own "primitive" past, which confronted scholars with the need to explain and justify the "superior" status of Western culture. Both ultimately paved the way for unrestrained racism. Evolutionistic, naturalistic, humanistic, clerical, and creationist visions competed in the scientific world, sometimes even merging in the convictions of individual scholars.

Key Issues/Current Debates

Paleolithic Mobile Art

Already in the first excavations, particularly in southwestern France, archaeologists found objects that did not quite fit into the picture of "primitive savages." According to popular beliefs, cultural performance in early societies had to be underdeveloped, and since art was considered to be one of the highest forms of cultural expression in the nineteenth century, the presence of figurative representations in Prehistoric deposits was an intellectual challenge. Édouard Lartet undertook excavations in, among others, Massat (Dept. Ariège), Le Moustier, Laugerie-Basse and Laugerie-Haute, Pech-de-l'Azé, and La Madeleine (Dept. Dordogne) (Lartet und Christy 1864, 1865). Many of these sites delivered skillfully decorated objects. The abovementioned engraved mammoth from La Madeleine offered unquestionable proof of the coexistence of humans and extinct animals (Lartet 1865). Other researchers added objects of this kind, like sculpted spear throwers from the Abris de Bruniquel, or the first prehistoric female figurine found, called the "Venus impudique," which was excavated in 1864 by Marquis Paul de Vibraye (1809–1878) in Laugerie-Basse. These artifacts testified that Prehistoric people were capable of artistic expressions and produced them regularly and skillfully. Art historians and scholars denied any deeper meaning with the artifacts and explained it in the sense of the then common *Zeitgeist* as "l'art pour l'art" – as a self-sufficient, aesthetic pleasure. Paleolithic or "primitive" men – more animal than human – lacked the capacity for developing religious ideas and expressing them in symbolic representations. Lartet and Christy developed a theory about the origin of art (Lartet und Christy 1864). They stated that art emerged in an ecologically favorable situation in which humans increasingly became independent of nature and used the free time to develop their aesthetic talents in a playful way. Producing art was a personal, and not a social, matter, and particularly gifted individuals became "artists."

The Debate About Altamira

In 1878, Sautuola had visited the Paris World Fair. He was interested in prehistoric objects from French excavations. Among them were examples of mobile artworks that have been recognized by the scientific community recently. After his daughter discovered the paintings in Altamira in 1879, he remembered these objects. The stylistic similarities between the mobile art and polychrome paintings in Altamira made Sautuola suspect that those are of Prehistoric age. In the paintings, which are executed on bumps and depressions of the ceiling and give the pictures a three-dimensional expression, Sautuola saw an echo of the animals depicted on the mobile objects. He consulted the Madrid geologist Juan Vilanova y Piera (1821–1893), who interestingly was a creationist (Sanz de Sautuola et al. 2004) but nevertheless shared Sautuola's opinion on the paintings in Altamira. In 1880, Sautuola published his discovery under the title *Breves apuntes sobre algunos objetos prehistóricos de la provincia de Santander* (*Brief Notes on Some Prehistoric Objects of the Province of Santander*) (Sanz de Sautuola 1880).

In *Breves apuntes*, Sautuola first describes the discovery of a cave at Revilla, where he carried out his own excavations. Among others, he found stone artifacts, animal teeth and bones, shells (*Patella* sp.), as well as modern bricks, tiles, earthenware, and prehistoric ceramics. The report on the cave of Altamira begins with a description of its location and extent of the galleries. In the main gallery, Sautuola describes a large deposit consisting of *Patella* sp., sea snails, animal bones and teeth, antlers, boulders, and stone artifacts in a layer of black ash material of about 1m thickness. He draws a comparison to Danish Kjökkenmöddings but refers explicitly to the lack of ceramics in the findings from Altamira. He then turns to the description of the paintings, which are located on the ceiling (Fig. 3). He discusses the size, the pigments used, and the animal species presented. He identifies most of the animals as bison. He describes the paintings as "produced with considerable skill" and that the artist "had a steady hand and there are no signs of vacillation. On the contrary, each trace was produced with one clean stroke, in spite of the irregular surface of the cave ceiling and whatever the tools the artist may have used to depict the animals" (translation in Sanz de Sautuola et al. 2004, 82). Next, he explains the different postures the artist must have taken – either kneeling or stretching up to the ceiling – and the fact that artificial lighting was necessary. For the second gallery, he mentions four geometric paintings in black and red (Fig. 4). In the third gallery, he describes fallen rocks and a single painting and in the fourth two more pictures. The access to the fifth gallery is particularly difficult, as one can only get in on all fours. In the small hall are numerous scratch marks, which Sautuola characterizes as made with a sharp tool. Not recognizing any patterns, he is considering the possibility that these could also be made by bats. In addition, he speaks about polished areas on the walls, which could have been caused by the rubbing of humans or animals. Consequently, and because of the presence of fallen blocks, he assumes that the entrance to this gallery must have been larger in prehistoric times. The ceiling of this gallery is covered with a thin layer of clay, with grooves that presumably were applied with fingers. He also describes five more paintings. When passing through the galleries, with the exception of gallery 1, black outlines are seen to the left and right, which correspond to each other.

In his conclusion, he states that the cave must have been inhabited either over an extended period of time or by a large number of people, proven by the abundance of animal bones and artifacts. In the different states of erosion of organic artifacts, Sautuola sees an indication for repeated settlement over a long time span. Concerning the quality of the paintings, he states that they are much finer in the first gallery than in the others. Nevertheless, he assumes that they have been applied simultaneously. The more difficult question to him is if the paintings and the archaeological layers correspond in time. Although he mentiones the excellent state of preservation of the paintings as an argument for a much later age than the deposition of the artifacts, he emphasizes that ocher pieces were found in the layers that could have been used for the paintings. To him, the fact that prehistoric humans were able to represent themselves and animals in mobile art carved in osseous materials offered uncontestable evidence that these people were capable of painting the same on cave walls. Although the presence of the extinct bison in the region was not yet proven, he quotes Georges-Louis Leclerc de Buffon (1707–1788), who attests to the presence these animals in many parts of Europe. He does not rule out the possibility that the paintings are of modern origin, but he argues that the cave was completely unknown at the time of its exploration. He does not doubt that the pictures are very old. The fingerprints in gallery 5 are especially in favor of this, as well as the fact that in gallery 1 there are animals that do not appear in the region around Altamira today. He classifies both caves mentioned in *Breves apuntes* as Paleolithic.

Initially, Sautuola's discovery was acknowledged by the public. Even the Spanish King Alfonso XII (1857–1885) visited Altamira. But shortly after, the first critics raised their voice. The strongest and most direct hostility came

from the regional scholar Ángel de los Ríos (1823–1899) in the Cantabrian press. He represented a conservative, religious viewpoint; this controversy took on slanderous tones. He accused Sautuola of having charged the artist Paul Ratier (1832–1896) with the forgery, whom he had entrusted with producing copies of the paintings and who regularly visited the cave (Figs. 3 and 4). The head of the Spanish National Chalcography Institute, Eugenio Lemus y Olmo (1843–1911), said that the paintings of Altamira were "the work of a mediocre disciple of modern art who neither knows how to pretend nor anything about the prehistoric period: it seems they wanted to simulate this period and [. . .] recruited the least appropriate artist to do so" (citation and translation in Sanz de Sautuola et al. 2004, 57). The *Institución Libre de Enseñanza* concluded that the paintings of Altamira were the product of Roman soldiers who sought refuge in the cave during the Cantabrian wars (29–19 BC). Also the debates under the auspices of the Spanish Natural History Society ended by denying the prehistoric age of the paintings (Sanz de Sautuola et al. 2004). Outside of Spain, French specialists were determined to reject the hypothesis of Sautuola, and his presentation was loudly mocked at the Prehistoric Congress of 1880 in Lisbon. The paintings seemed too old, too magnificent, too well made, and too well preserved. Even the support of renowned scholars like Juan Vilanova and Édouard Piette did not help him (Sanz de Sautuola et al. 2004).

Émile Cartailhac (1845–1921) was one of the most important and influential prehistorians of his time (Fig. 2). He conducted excavations at the dolmens of Aveyron, in Portugal, Iceland, and the Balearic Islands. He was the curator of the Prehistoric Department of the Paris World Fair in 1867 and chief editor of the magazine *Matériaux pour l'histoire naturelle et primitive de l'homme*. From 1882 he taught at the University of Toulouse, and in 1897 he became curator of the *Académie des Jeux floraux*, the oldest scientific society in Europe. He co-founded the Saint-Raymond Museum in Toulouse and was one of the first editors of the journal *L'Anthropologie*. Cartailhac was one of the strongest opponents of

From Sautuola to Cartailhac, Fig. 2 Émile Cartailhac (Muséum de Toulouse)

Sautuola's discovery. He sent the paleontologists Édouard Harlé (1850–1922) to inspect the paintings of Altamira. Harlé reported that although the archaeological deposits in Altamira were indeed Paleolithic, the paintings were modern (Sanz de Sautuola et al. 2004). Cartailhac called the paintings a "vulgar prank of a dauber" – it would not even be worthwhile to look at the pictures. His rejection led to the cave of Altamira and its explorer Sautuola to be tacitly ignored at all congresses. The excellent preservation seemed to confirm their suspicions, and scholars did not believe that "primitive" humans were capable of such great works. Small carvings without symbolic content were acceptable; great paintings removed from the traces of everyday life in caves, executed with large effort and care, probably as parts of rituals, were inconceivable. And so the cave of Altamira fell into oblivion for more than 20 years. Pained and stunned by the rejection of the scholars, Sautuola had the cave closed. He died in 1888, embittered and without his discovery being recognized.

The Acceptance: *Mea culpa d'un sceptique*

Cartailhac remained unyielding. Even when Édouard Piette, who was convinced of the authenticity of the paintings in Altamira, asked him a year before Sautuola's death to review his assessment, he did not engage. It took about 20 years until it came to reconsideration. Similarly to the history of scientific acceptance of the Neanderthal skeleton, more and more Paleolithic painted caves were reported. In 1895, the cave of La Mouthe (Dept. Dordogne) was discovered, containing paintings and engravings of bison and a beautiful stone lamp whose dating to the Ice Age was beyond dispute. Further caves were discovered: in 1896 Pair-non-Pair (Dept. Gironde) and, subsequently, in 1901 Font-de-Gaume and Les Combarelles near Les Eyzies-de-Tayac-Sireuil in the Dordogne, and the doubts about Sautuola's discovery dwindled. In 1902, Cartailhac visited Altamira together with the young Abbé Henri Breuil (1877–1961) for the first time and met María Sanz de Sautuola (Cartailhac and Breuil 1903). He apologized to her and promised her to do everything to clear Don Marcelino's name. In a letter from 9 October 1902, he says: "We live in a new world."

He admitted his mistake in the article *Les cavernes ornées de dessins. La grotte d'Altamira, Espagne. Mea culpa d'un sceptique*, published in the *L'Anthropologie* (Cartailhac 1902) – 22 years after the publication of *Breves apuntes*. He accused himself of "an error, committed twenty years ago, an injustice that it is essential to public acknowledge and make amends for . . . It is necessary to face the reality and, as far as I am concerned, I must do justice to M. de Sautuola" (Cartailhac 1902; translation in Sanz de Sautuola et al. 2004, 62). He repented holding back the progress of science and harshly criticized himself for doing an injustice to an honest man and rejecting his discovery without any investigation. Today, the opinions about Cartailhac's *Mea culpa* differ. While most see it as a humble and honest gesture of a great man, who was not afraid to admit his error publicly (e.g., Lasheras and de las Heras in Sanz de Sautuola et al. 2004), there are also skeptics who consider this as a well-calculated move, as his own position was no longer tenable under the oppressive burden of proof (Lewis-Williams 2002; Figs. 3 and 4).

International Perspectives and Future Directions

Cartailhac himself examined the cave of Altamira together with the young Abbé Breuil. This resulted in the monograph *La Caverne d'Altamira à Santillane près Santander (Espagne)* (Cartailhac and Breuil 1906). In 1935, after careful excavations and first conservational actions, a second monograph by Breuil and Hugo Obermaier (1877–1946) in English followed (Breuil and Obermaier 1935). While the cave of Altamira achieved great fame, Sautuola's sophisticated and ingenious deduction was downplayed in numerous publications and not adequately appreciated. This is partly due to his cautious formulations in *Breves apuntes*, but also because of the low prevalence of this excellent study (sees Sanz de Sautuola et al. 2004, 64–65). In his short essay, Sautuola proves an exemplary grasp of lines of interpretation and argumentation necessary for the understanding of archaeological remains. In addition, he shows an openness for foreign and past cultures, which he describes as "not progressed very far along the road to civilization" (translation in Sanz de Sautuola et al. 2004, 55), without classifying them as "primitive" or "savage." In addition, he states about the artist of Altamira that "the author possessed a developed aesthetic sense" (translation in Sanz de Sautuola et al. 2004, 56) – in contrast to the then-common view of aesthetics, which was still dominated by the style of old masters and showed no sense for modern stylistic features as abstraction, the play of colors, or exaggeration (Fig. 5).

With the discovery of other painted caves, the view on Paleolithic art changed. Abbé Breuil dedicated much of his work to the exploration and documentation of Paleolithic cave art. He used ethnological comparisons to understand the works of art and interpreted them as part of hunting-magic rituals. His student André Leroi-Gourhan (1911–1986) already had such a large assemblage to investigate that he was able to establish a chronology of Paleolithic art on the basis of stylistic criteria, which has been partly confirmed by modern dating methods. Today, researchers can study countless painted and

engraved caves, rock shelters, and open areas in many parts of Europe from Spain to the Ural Mountains. Nobody questions the high craftsmanship of Paleolithic artists anymore. The legacy of these early artists continues to exert a unique fascination. Painted caves had to be closed or severely restricted for the public traffic due to conservation problems. Many of the caves, including Altamira (Fig. 5), have been designated UNESCO World Heritage sites and their faithful replicas attract hundreds of thousands of visitors each year.

Frost, Honor

Angela Croome
Nautical Archaeology Society, Portsmouth, UK

Basic Biographical Information

Honor Frost (1917–2010) was born and brought up in Cyprus surrounded by the sea. The lands of the Eastern Mediterranean retained her loyalty throughout her life. Of Byblos in the Lebanon, she wrote late in her career "this is where I belong." She learnt her diving at the Nice Divers Club when convalescing and where Cousteau's original team hung out. They introduced her to amphora wrecks from antiquity that stimulated her interest in submerged archaeology. She had already had a ballet staged by Ninette de Valois in London and attended art school which refined her drawing skills which she readily applied underwater. She joined the last season of Kay Kenyon's excavations of Jericho as draftsperson. This gave her a flying start in surveying stone structures underwater, the telltale remains of 11 ancient harbors along the shelterless Levantine coast. Stone anchors that marked ship graveyards also became an obsession.

Major Accomplishments

A chance encounter with a sponge-diver at Bodrum, South Turkey, brought about the discovery of a twelfth-century BCE Bronze Age wreck deposit which made her famous and put underwater archaeology on the map. It was the first deep-water site to be excavated to land archaeology standards and focused the Anglo-American world on the new discipline. The cargo of ingots and bronze scrap suggested a traveling tinker's workshop benefiting from the contemporary Trojan War. Honor's 1963 best-seller *Under the Mediterranean* describes this period, and she was soon to be invited by UNESCO to provide a guide for international consumption – *Underwater Archaeology, A Nascent Discipline* (1972) – which was highly influential and made her something of a world mentor for budding archaeological divers.

As 1970 opened, Honor led a project that resulted in the discovery and excavation of a third-century BCE Punic warship off Sicily. This time, it was a fisherman who reported bringing up very old timbers from the site of a sea battle with the Romans. It was the first time than an ancient warship had been discovered intact. Honor's Punic ship showed through matching marks on the timbers that the ancients used prefabrication to build an entire fighting fleet in months. It took rather longer to reconstruct and put on display but became in effect Italy's *Vasa*.

Honor Frost was now the world authority on stone anchors as well as the lost harbors of antiquity submerged by sea level and climate change. Among her other achievements were over a 100 scholarly publications, the initiation in 1972 of the unique *International Journal of Nautical Archaeology* (still the lead journal in this subject), and her promotion of best practice and innovative techniques. In one hundred years time, she will probably be best known for the fruit of her legacy of £30,000,000 for the encouragement of nautical archaeology research, particularly in the Eastern Mediterranean.

Introduction

Frozen sites provide unique opportunities to understand the full range of a people's material culture. From frozen bodies to intact multi-component artifacts to wooden structures to faunal remains and macrobotanical remains, these sites can lead to unparalleled insights into cultures and paleoenvironments. The special challenges of excavation include the need for multiple specialties in the field, the typical need for a field laboratory, multiple seasons to allow the site to thaw, and extraordinary logistical costs. Global warming has greatly increased the challenges.

Definition

Various types of sites and contexts frequently demonstrate long-term frozen conditions. There are some differences among them that influence preservation conditions and determine choices for excavation techniques. These include permafrost, cold dry sites (polar or alpine), ice patches, and glaciers. About one-quarter of the earth's land area carries permafrost. Where continuous, it is typically hundreds of meters deep. Further south, discontinuous permafrost is tens of meters deep. In the first International Polar Year, the Point Barrow Expedition personnel spent 2 years (1881–1883) digging to find the bottom of the permafrost. They never found it but did pass through an archaeological deposit (Murdoch 1892). Upon the end of the expedition, they left behind what for many decades was the deepest ice cellar in the Native Iñupiat Eskimo community of Utqiaġvik.

Permafrost

The technical definition of permafrost (permanently frozen ground) is soil, sediment, or rock that remains at or below 0 °C for at least 2 years. When applied to archaeological sites, the term generally refers to sites in which cultural materials and the surrounding matrix have remained frozen essentially since they were deposited. Depending on the regional climate, if there is not enough overburden to insulate the cultural deposits, the upper levels of a site (the active layer) may go through freeze-thaw cycles. During the unfrozen period, underlying frozen ground can trap melting water at the surface, creating waterlogged conditions, which aid preservation. Excellent examples of permafrost sites include Utqiaġvik (Hall and Fullerton 1990; Sheehan 1997), the Zhokhov and Yana River RHS sites in Siberia (Pitulko 2001, 2008; Pitulko et al. 2004), and Qeqertassuk (Grønnow 1994; Meldgaard 2004).

The depth of the active layer varies with the type of matrix. Permafrost sites can be found in gravel, as at Nuvuk (Jensen 2009), in tundra soils as at Utqiaġvik (Hall and Fullerton 1990), and in sand as at Pingusugruk (Sheehan 1997). The looser the matrix, the deeper the active layer. The deeper the active layer, the more potential damage to more recent (higher) levels of an otherwise permafrost embedded site.

People in cold regions often found the most effective protection from the cold was to get out of the wind. Lacking trees and often lacking any natural windbreaks in prime locations, as in the Arctic Coastal Plain, this protection often was assisted by excavating structures into the permafrost and insulating them with grass sods. The inadvertent result was increased preservation. In a house whose floor lay in the permafrost, freezing started immediately once there was a lack of a heat source, whether a seal oil or whale oil lamp or a fireplace, and a lack of human body heat.

Cold Dry Sites

In cases where the surrounding environment is extremely dry (alpine or high arctic deserts), or the matrix has a low organic content and is well-drained, organic materials in a site essentially can be freeze-dried. While such sites may meet the technical definition of permafrost, the lack of moisture creates somewhat different preservation conditions and excavation issues. Good examples of dry sites are Mount Llullaillaco in Argentina (Reinhard and Ceruti 2010) and Qilakitsok in Greenland (Meldgaard et al. 1991).

Ice Patches

Ice patches are not massive enough to form glaciers. They are permanent ice or snowfields that do not melt away over the summer and that continue to accumulate and turn to ice. They attract animals such as caribou, serving as summer insect relief areas. The animals have attracted hunters over millennia. Animal dung and artifacts have been preserved frozen in the ice.

Warming climate is melting back the patches, so that previously hidden materials can be exposed annually. If not collected very quickly, they will decay or be destroyed by caribou trampling. Ice patch archaeology is now a vibrant field, beginning with finds in the Canadian Yukon in 1997. Examination of nearby ice patches as part of a project during the fourth International Polar Year led to finds at additional locations. Europeans have been finding archaeological materials in ice patches for much longer. Known concentrations of ice patch sites include Wrangell-St. Elias National Park and Lake Clark National Park in Alaska; Rocky Mountain National Park and the Greater Yellowstone in the US Rocky Mountains; Mackenzie and Selwyn Mountains between the Yukon and Northwest Territories in Canada; Oppdal, Oppland County, and Finnmark in Norway; and the Swiss Alps (Andrews and MacKay 2012; VanderHoek et al. 2012; Reckin 2013; Dixon et al. 2014).

Glaciers

Glaciers can contain what could be considered archaeological sites, although they are usually encased in a moving matrix of snow and/or ice. The majority developed when some form of material culture (e.g., crashed aircraft, scientific research stations) was deposited on the glacier's surface layers and then covered by snow.

As glaciers move they develop crevasses that change the relative position of items, so glacial sites generally lack integrity. Even large aircraft

can be torn apart in a few decades. For this reason, archaeologists rarely deal with such "sites."

Sometimes an advancing glacier covers an existing site that is protected by terrain from the moving ice. These sites can be revealed when the glacier retreats. The most famous find from such a site is Ötzi, the "Iceman" who was recovered with many of his belongings from a gully in the Italian Tyrol (Höpfel et al. 1992). He had died in the gully and was found shortly after glacial retreat exposed him.

Key Issues/Current Debates/Future Directions/Examples

Preservation in Frozen Sites

Frozen sites are generally protected from insects and digging creatures. Roots from vegetation cannot penetrate them. More recent human occupations typically do not excavate very far into previous occupations, since digging into permafrost requires almost the same effort as digging into concrete. This often results in superimposed stratigraphically intact cultural levels that can cover periods of thousands of years and multiple cultural designations.

Deterioration typically seen in organics at unfrozen sites is delayed. Frozen conditions allow for the preservation of a wide range of organic material in addition to the inorganic materials that are more commonly found at archaeological sites. Most chemical and biological processes slow in cold conditions, almost stopping at temperatures below freezing. Freezing of organic remains like a human body or an animal carcass does eventually result in dehydration, even if the freezing is accomplished in a pool of water that turns to ice (Zimmerman et al. 2000). This creates the possibility of very detailed cultural and paleoenvironmental studies if proper samples are collected and retained.

The active layer in permafrost is the soil or level that actively thaws each summer, starting at the ground surface and penetrating repeatedly to roughly the same depth in any given location. Materials below the active layer are permanently frozen. Those in the active layer are frozen for much of the year. In most cases, the long periods of freezing seem to have outweighed the brief annual thaws, despite the disruptions to preservation that thawing and freezing can induce or allow.

Excavation for Maximum Preservation

Significant portions of standing structures can be preserved when buried in permafrost. Organic artifacts can outnumber lithics in frozen sites 100 to 1, rewarding fieldwork with assemblages rarely seen in most of the world. Interpretation of past lifeways is likely to be more successful thanks to this much more representative sampling of material culture. However, excavation of frozen sites is technically demanding, the logistics are complex and expensive, and analyzing and conserving the resulting collections can be challenging. Successful excavation in frozen sites requires a good deal of planning. The use of geophysical techniques can facilitate excavation planning if the logistics can be accomplished (Urban et al. 2016).

The cost of stabilizing and then permanently storing wooden architectural components after documentation and sampling can be prohibitive. On-site burial deep in the permafrost below the active layer may be the best option. Erosion and increased depth of active layers due to global warming must be taken into account. Refreezing important organics may be the best way to maintain integrity after analysis in the laboratory. This requires a long-term institutional commitment to freezers and their maintenance. Even conventional museum storage for such large, organic-rich collections, including bulk samples for analyses like sedaDNA (Seersholm et al. 2016) can be problematic given the current curation crisis at museums. Costs for frozen sites fieldwork are already high due to remoteness, the need to work with the daily thaw rate, extremely short "warm" seasons, and the need for representation of multiple skilled disciplines on-site and during analysis.

The often-spectacular preservation of the spectrum of human material culture plus processed and unprocessed animal products and sometimes the presence of frozen human remains ideally requires a large multidisciplinary field crew, many of whom might be confined to a laboratory

during excavation of less well-preserved sites. Specialists may attend to architectural elements, to multicomponent artifacts that incorporate organic and inorganic materials, and to faunal remains. Wood specialists and clothing specialists, especially for fur and hide, are desirable. Also, aDNA specialists must be present to retrieve uncontaminated samples successfully.

Competent polar bear guards must be employed in some locations in order for staff to focus on fieldwork. Experienced field hands and camp and logistics managers, field laboratory supervisors, and staff are all required to take advantage of the pristine status of materials on the day they are removed from the ground, pristine status that cannot be maintained without prompt and constant attention during what can be a long period of partial exposure. It may be days before an item can successfully be removed, so this attention must start as artifacts are first revealed in the frozen levels. During this period, preservation must be maintained until the item can be extracted and moved to the field laboratory.

The slow rate of thaw after exposure typically means that sterile soil cannot be reached in a single season. Funds for multiple seasons are necessary to recover a site's archaeological history successfully. Sondages can be impossible thanks to permafrost. Part of a season's fieldwork is working to preserve the site's integrity for the following season. Many reviewers are shocked by the cost of proposals for frozen sites archaeology and unfortunately do not get past it to consider the value of data from sites where "everything ever left at the site" is still there and still in very good condition.

The Good and the Bad of Frozen Conditions On-site and in the Laboratory

Frozen soils can be subject to a process called solifluction, where soils move and flow downhill. This can considerably disturb site integrity, sometimes folding strata and causing stratigraphic reversals. Frozen sites can be more cohesive than the natural strata below them. When the sites are elevated and on the coast, as at Utqiaġvik (Mason 1991), entire stacks of superimposed semi-subterranean houses can be undermined by wave action and can fall en bloc onto the beach or into the water, rotating as they fall and resulting in tilting or reversed stratigraphy until thawing and erosion eliminate the evidence (Fig. 1). Similar effects can occur when sites in areas of ice-rich permafrost overlie large ice wedges, which can melt and drain away, leaving voids under sites.

In conditions where patterned ground forms, if sufficient water is present, new ice wedges can develop, and they also can affect the integrity of the site as a whole. This generally takes the form of separate chunks of the site moving relative to each other.

Frozen Conditions: Preservation and Excavation, Fig. 1 Slump block on the beach. Walakpa, view north

Frozen conditions can greatly slow, if not entirely stop, biological and chemical processes which cause the decay of organic materials. Thus, the period of time that organic materials can be preserved is extended well beyond that which could be expected for the same materials in unfrozen conditions. This makes possible both highly detailed cultural analyses and paleoenvironmental reconstruction.

Freezing is not an unmixed blessing for artifacts and organic remains. Freezing water expands, potentially damaging them. Ice crystals form in moisture-bearing materials as freezing occurs. The size of the crystals depends on the speed of freezing, with smaller crystals forming with faster freezing and larger crystals doing more structural damage. Ice crystals damage organic materials' cellular structure. Since past freezing and thawing of organic artifacts may have damaged cellular structures, artifacts can appear in excellent shape when first excavated and then deteriorate rapidly. Many artifacts from permafrost sites have high moisture content, requiring slow drying to avoid serious cracking. Lithics tend to split into plates in a process called frost spalling, particularly artifacts manufactured from softer sedimentary rock such as sandstone.

It is sometimes possible to stabilize certain classes of materials in the field or a field laboratory. Field options may be limited by equipment and compounded by airline safety regulations that limit transport of some important chemicals. In some cases, treatment by a conservator in a fully equipped laboratory is the only practical solution.

It can be difficult to find a conservator to assist in the field, since most frozen sites contain a very wide range of materials, and conservators are becoming more specialized. They are often employed by institutions that do not wish to be without their services for months at a time.

Again, funding is generally a limiting factor. It has been fairly standard practice for many decades not to apply any conservation treatments to faunal collections from frozen sites. In addition to reserving funds for the conservation of artifacts, this has the advantage of avoiding contamination to bones and keeping them suitable for use in aDNA, stable isotope, trace elements, and other analyses that were not anticipated when the practice was first adopted.

Long-Term Prospects for Frozen Sites

Long-term prospects for frozen sites are very concerning (Figs. 2 and 3). With a warming climate, ice patch sites are rapidly disappearing. Already some newly discovered ice patches, which held materials of more than a millennium in age, have disappeared. Most known sites are coastal or next to bodies of water and subject to erosion. Comparatively little inland exploration

Frozen Conditions: Preservation and Excavation, Fig. 2 Remains of the house and ice-filled tunnel exposed and undercut by erosion. Nuvuk, view south

Frozen Conditions: Preservation and Excavation, Fig. 3 House timbers slumping due to permafrost collapse and erosion. Utqiaġvik, view southwest

has been accomplished. Inland sites are therefore less well documented and threats to their integrity are less well understood.

As climate warms, so does permafrost. The depth of the active layer is increasing around the Arctic, which means that sites and artifacts previously in stasis are being exposed to repeated freeze-thaw cycles with longer annual opportunities for chemical and biological decay-producing processes to act (Hollesen et al. 2015). In Alaska, predictions are that the active layer may reach 2 m in depth even in the northernmost part of the state by 2100 AD (Murray et al. 2011).

For coastal sites, rising sea level and less marine ice cover increase erosion. As threats increase to these sites, and as their potential to contribute to our understanding of human culture and past environments is better understood by reviewers and the general public, we can expect more research. The best archaeological record of cultures adapting to rapid climate change is found in frozen sites dating to the last major warming period, roughly a thousand years ago. To better understand how we can adapt to current climate warming, we should more thoroughly understand how people did it a thousand years ago.

Fullagar, Richard L. K.

Lesley Head
University of Wollongong, Wollongong, NSW, Australia

Basic Biographical Information

Richard Fullagar is an Australian archaeologist and a Founding Director of Scarp Archaeology. He grew up in Melbourne, Victoria, and completed his Higher School Certificate in 1972. He completed a B.A. at the University of Melbourne in 1977, picking up archaeology as a fill-in subject, and worked for the Victoria Archaeological Survey (VAS) from 1978 until 1983. He went on to complete a Ph.D. in archaeology at La Trobe University in 1986.

While at the VAS, he undertook numerous surveys and excavations on the Victorian coast and along a transect running north from Warrnambool (through the Western District, the Mallee, and the Little Desert) to the Murray River. He also undertook field research in the Philippines, initially with Peter Coutts (Director, VAS) and later on his own. He has lived in Wollongong since 1987 and has held Australian Research Council (ARC) Fellowships at the Australian Museum (Sydney) and the University of Sydney.

Fullagar has undertaken collaborative projects with colleagues in the Netherlands, Belgium, and South Africa and developed broad interests in hunter-gatherer lithic technology, the history of plant food processing, and modern human dispersal into Australia.

He is one of Australia's most experienced field archaeologists, having undertaken research projects in all states of Australia and in Papua New Guinea. Fullagar received ARC support for projects in West New Britain, Papua New Guinea; the Keep River area in the East Kimberley; Cuddie Springs, Western NSW; and Riversleigh, Northwestern Queensland. He is a Chief Investigator on two current (2011–2015) ARC projects: one to re-excavate early archaeological sites in

Australia and Timor and the other to undertake collaborative research into wetlands with Aboriginal groups in New England and Tasmania.

Dr. Fullagar is a founding Director of Scarp Archaeology (established 2007), a company that focuses on cultural heritage management projects and related research in the Pilbara (WA) and the Hunter Valley (NSW).

Major Accomplishments

Building particularly on the work of Johan Kamminga and Tom Loy, Richard Fullagar pioneered the integration of lithic usewear and residues in Australia. He was the first Australian to systematically study usewear and residues of stone tool assemblages under vertical incident light microscopes. His initial work focused on use-polishes and plant residues, notably starch grains, to reconstruct food processing and ancient diets. He advocated the use of different microscope types and initiated the establishment of microscopic usewear/residue laboratories at La Trobe University, Australian Museum, University of Sydney, and University of Wollongong, where he is currently Honorary Principal Fellow in the Centre for Archaeological Science, School of Earth and Environmental Sciences. He has advised several other institutions on appropriate facilities for similar laboratories.

He has made important contributions to archaeology in Australia, New Guinea, and the Asia-Pacific. Much of his work has been in the form of specialist stone tool studies linked with diverse archaeological projects in Australia, Papua New Guinea, Asia-Pacific, and Africa. Research highlights over the last 35 years include identification of 28,000-year-old seed-grinding tools at Cuddie Springs, Western NSW; excavation and dating of Jinmium rockshelter, Northern Territory, Australia; and the discovery of 10,000-year-old taro-processing tools from Kuk Swamp, PNG.

Dr. Fullagar has authored or coauthored more than 65 technical and consultancy reports, three edited volumes, and 115 journal articles and book chapters. He has taken a special interest in public engagement with 65 contributions published regularly from 1999 to 2006 in *Nature Australia*, the Australian Museum's award-winning magazine (now discontinued).

Dr. Fullagar has served on the Executive of the Australian Archaeological Association (AAA) and is a past President of the Australian Association of Consulting Archaeologists Inc. (AACAI). He was awarded the inaugural AAA Bruce Veitch Award for Excellence in Indigenous Engagement in 2006.

Funari, Pedro Paulo A. (Historical Archaeology)

Andrés Zarankin
Departamento de Sociologia e Antropologia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Basic Biographical Information

Pedro Paulo Abreu Funari was born in Sao Paulo, Brazil, and earned his Bachelor's Degree in History at the Sao Paulo University (USP) during the early 1980s. He has specialized in Ancient History and Classical Archaeology, with special emphasis on the subject of olive oil circulation within the Roman Empire. He continued to develop this theme for his Masters in Social Anthropology and doctoral studies in Archaeology, under the supervision of Professor Haiganuch Sarian. During this process, Funari continued specializing in material culture studies, while attending internships at the USP Archaeology and Ethnology Museum. In the latter, he participated in several excavations and archaeological projects, such as the amphora's research, and the Pompeii graffiti and paintings' study (Funari 2002).

In 1992, Funari became part of UNICAMP History Department as a professor. Since then he has continuously taken a leading role in the promotion of archaeological investigations at the university, transforming it into a center of excellence in archaeological studies and formation. Currently, he is a professor at the History Department of Campinas State University (UNICAMP), and coordinator of the Advanced Studies Institute (UNICAMP).

Major Accomplishments

In the 1990s, Funari organized a project of Historical Archaeology in collaboration with American Archaeologist Charles E. Orser and British Archaeologist Michael Rowlands, studying the Barriga Ridge. This site was the former capital of the Palmares Quilombo in the seventeenth century. Sponsored by Brazilian, American, and British funding, the excavations were very important as they revealed the Archaeology of the Subaltern for the first time in Brazil (Orser and Funari 2001; Funari 2006).

Another field of interest to Funari has been the History of Brazilian Archaeology. Considering ideological and historical contexts through a critical perspective, he has focused on how they have influenced the process of succession among different schools and theoretical trends in the Brazilian context (e.g., Funari 1999; Funari and Menezes Ferreira 2006).

Most recently, Professor Funari has been introducing Brazil to important discussions regarding the archaeological practice, the political enrollment of archaeologists inside the local communities with whom they work, and the building of the past and its effects on the present, among other issues. Therefore, the creation of the Public Archaeology Center in UNICAMP is the result of all these debates envisioned through the public archaeology perspective (e.g., Funari 2004, 2009). Among Latin-American archaeologists, Professor Funari has one of the greatest scholarly productions and enjoys regional and worldwide recognition (Funari et al. 1999). He has published several books and more than 300 articles. A confirmation of his success is his vast work that has become a reference in several fields,

such as Classical Archaeology, Historical Archaeology, Archaeological Theory, the History of Brazilian Archaeology, and Public Archaeology.

Funari, Pedro Paulo A. (Indigenous Archaeology)

Marcia Bezerra
PPGA/Universidade Federal do Pará/CNPq, Belém, Pará, Brazil

Basic Biographical Information

Pedro Paulo A. Funari (1959–) was born in São Paulo, southeast of Brazil, to a family of humble origins but adept to reading and to culture in general (Fig. 1). Influenced by the family environment, he became, at a young age, interested in the humanities, specially philosophy, politics, and religion. Philosophy would have been his choice for ingressing in higher education, but the political context of Brazil in the 1970s – the military dictatorship – forced him to choose another path: history. The undergraduate major in history at the Universidade de São Paulo/USP, between 1977 and 1981, however, allowed his insertion in a forum of reflections on the social injustices, in particular, on the political panorama of Latin America (one of his constant concerns)

Funari, Pedro Paulo A. (Indigenous Archaeology), Fig. 1 Funari, Pedro P. de A. (Brazilian archaeologist)

and, at the same time, granted him the right to lecture history. For Funari, the teaching of history at the time fulfilled two roles: the chance to share with his students a more critical view of history and of society and his ingressing in a field of work that would permit the improvement of his studies. His proposal to study the military dictatorship right at the time of the military regime, however, did not find echo at the academic environment of freedom curtailed by the authoritarian government. Once more, the opting for another path was necessary. This was how ancient history became one of his major areas of interest. While developing research on olive oil in ancient Rome during his Masters in Social Studies (Anthropology) at the Universidade de São Paulo, between 1982 and 1986, Funari came across the field of study of material culture, which would come to define a significant part of his career. The research on ancient ceramics was further developed during the Doctorate in Archaeology at the Universidade de São Paulo, between 1986 and 1990, period in which he undertook various research trips and internships in renowned teaching and research institutions in Europe. His fluency in various languages enhanced these experiences, leading him to establish contacts and partnerships with distinguished foreign researchers. His international career consolidated itself between the years of 1992 and 2004, a period in which he conducted 6 postdoctorates in universities of Brazil, the United States, Spain, and England. In 1992 he became professor of the Universidade Estadual de Campinas/UNICAMP, one of the most prestigious universities in the country, where he works until today. At UNICAMP, Funari coordinates groups and research projects related to classical antiquity, to politics, and to archaeology and edits periodicals such as "Arqueologia Pública." Besides being editor of over 40 foreign and Brazilian scientific publications, he has published over 100 books, 190 book chapters, and 490 articles in Brazil, other countries of South America, Europe, Oceania, and the United States.

Major Accomplishments

His extraordinary academic production, summed to the political activism which characterized his career, has made him respected by colleagues in various countries, which resulted in his indication as Southern American Representative (1994 and 2002) and Secretary of World Archaeological Congress (2002 and 2003). In Brazil, Funari has occupied various positions in scientific societies in the history and archaeology areas. His political inquietudes, arisen while still in his youth, have always accompanied him. A tenacious critic of dominant ideologies – inside and outside of the academy – Funari has formed a generation of researchers concerned with establishing more humane and solidary academic relations. His vast bibliographical production includes such themes: dictatorships in Latin America, slavery, postcolonialism, education, teaching of indigenous history, critique of archaeology, public archaeology, and heritage, therefore of issues that involve reflection on power relations in the past and in the present. His formation in history, social sciences (anthropology), and archaeology allows his ideas to transit between distinct domains of knowledge and reach diverse audiences. One of the most cited authors in Brazilian archaeology at present time, Funari is author of the first book on introduction to archaeology in the country. The book "Arqueologia," released in 1988 and reedited in 2003, is widely used by students of archaeology and related areas as well as by teachers of diverse areas. Also of his authorship is the first book on Brazilian prehistory in an accessible language to a main audience (Funari and Noelli 2002). In 2001, he published a book that presents the precolonial history of Brazil to child and teenage audiences. Recently Funari released, in coauthorship with Spanish researcher Ana Piñon, a book that discusses the indigenous theme in school for teachers (Funari and Piñon 2011). Such category of literature demonstrates one of the most marked characteristics of this acting archaeologist and historian: his concern with the formation of students and teachers and the democratization of science in Brazil. Pedro Paulo A. Funari is a brilliant researcher who possesses the rare ability to stimulate vocations. In his teaching career, he has supervised 12 postdoctorates, 23 doctorates, and 31 masters in Brazil and abroad. Funari has a strong political commitment to archaeology and a solid dedication

to his students, with whom he has shared authorship in articles and books in Brazil and abroad. Currently (2012), Funari directs the Center for Advanced Studies, founded by him in 2009, at UNICAMP and is an associated faculty at the Universidade de Algarve (Portugal), Universidad del Centro de la Provincia de Buenos Aires (Argentina), Illinois State University (United States), Universidad de Barcelona (Spain), and various Brazilian universities. His passion for academic life, allied to his combative – but elegant – political positioning against hierarchies, has attracted many young and restless students that, such as young Funari, aspire to social relations that are less unequal, inside as well as outside of archaeology.

Funerary Customs and Religious Practices in the Ancient Near East

Nicola Laneri
Center for the Ancient Mediterranean and Near Eastern Studies, Florence, Italy

The death of an individual represents a moment of tragic and unexplainable loss for the members of a community that reveals the need and consequent desire to create beliefs about the existence of an afterlife. For numerous scholars this aspect of human life represents the beginning of a long-term evolutionary process that generated the development of forms of religiosity, dating back to the earliest members of the human species.

In general, the evolutionary approach that was developed by nineteenth-century Victorian anthropologists connects the belief that when an individual dies, a nonphysical soul departs from the physical body to the beginning of religious phenomena (i.e., animism), which is the basis from which more complex forms of religious beliefs developed over time. According to Tylor's seminal perspective, among "primitive cultures" it is possible to distinguish between a more basic and general belief in the soul of the deceased that serves the purpose of a "continued existence after

the death or destruction of the body" and more complex forms of belief in spiritual beings "upward to the rank of powerful deities" (Tylor 2016, I: 426). For him, spiritual beings are those immaterial entities that "affect or control the events of the material world, and man's life here and hereafter" (ibid., I: 426).

In the Near East, elements of early forms of belief in the afterlife of human spirits are recognizable in the burial of Paleolithic corpses found deposited in the rock caves of Shanidar in northern Iraq. Here, the burial of individuals is found in association with a few artifacts and, especially, trace remains of flower pollen.

These early attempts to cope with death represent a first step toward the creation of beliefs in something outside of the physical realm, as well as the search for the immortality of the soul and the creation of spiritual entities, all of which play a fundamental role in shaping people's lives throughout the history of ancient Near Eastern communities.

Drawing upon these premises, the aim of this contribution is to investigate how funerary customs and religious practices transformed throughout the history of the ancient Near East. The rich and varied examples available from the region span thousands of years, allowing us to trace the emergence of important elements from the cult of the ancestors and the subsequent creation of enclosures in which ritual practices were performed more than 10,000 years ago in southeastern Anatolia and the Levant, to the beginning of complex forms of polytheism in Mesopotamia starting from the fourth millennium BC, to the emergence of the first example of monotheistic religiosity (i.e., Judaism) in the Levant during the first millennium BC.

The Cult of the Ancestors During the Neolithic Period

One of the first steps in defining a link between funerary customs and religious beliefs is clearly related to how, within a given community, the cult of the dead was transformed into a cult of selected deceased, otherwise known as the cult of the ancestors. The idea that the spirit continues to live beyond the death of a family member is a defining factor of ancestor worship in the Near East, and this belief explains the needs for humans to have an ongoing relationship with the dead through funerary feasts, prayers, and offerings. In this way, the physical death of the deceased does not imply a rupture of the relationship between the living and the deceased but rather becomes an opportunity to reinforce family ties through a series of reciprocal obligations.

Since prehistoric times, the manipulation of human skulls illustrates that ancestral cults were deeply embedded in the traditions of ancient Near Eastern societies, through actions ranging from the removal of skulls from corpses to their caching, deformation, and, in some cases, decoration (Verhoeven 2011). This tradition was part of the so-called skull cult, a ceremonial practice that started during the Natufian period (ca. 12,500–9500 BC) and was enacted until the Late Neolithic (ca. 6200 BC) from the Levant all the way to southeastern and central Anatolia.

Even though the manipulation of the human body is recognizable since the Late Natufian period, it is particularly during the Pre-Pottery Neolithic (PPN, ca. 9500–7000 BC) that the custom of decapitating selected deceased and using the skulls isolated or grouped in caches becomes an element of commonality among groups that were slowly moving from a nomadic to a more sedentary form of living. This is especially the case of the Levant during the Pre-Pottery Neolithic B, when plastered skulls were found in caches either buried in pits at the end of their life history, such as those found at Jericho, 'Ain Ghazal, Beisomoun, and Kfar HaHoresh in southern Levant, or displayed above ground, as in the case of the four plastered skulls discovered at Tell Aswad in western Syria (Kuijt 2008; Verhoeven 2011). The skulls are of both sexes and of all ages and were removed after burial of the dead body. According to Croucher (2012: 303), "plastered skulls were intended to be displayed rather than kept permanently hidden or stored," and they were used as part of religious cults (probably

F

associated with the memory of the ancestors) in ceremonial practices that served to connect ties among early agricultural communities in a transforming (and probably stressful) social and cultural environment.

In this process, the body (or part of it) has been reused after its initial burial in graves both intramurally (the highest number of cases) and extramurally, constituting a form of construction of social memories of the ancestors through the circulation of body parts of the selected individuals. Thus, as mentioned by Kuijt (2008: 183), "Neolithic secondary mortuary practices are a form of bodily recirculation." In so doing, the selection of body parts was also used as a form of selecting the deceased and introducing their memory in the daily life of the other components of the community. Within this framework, the creation of religious dimensions by the Pre-Pottery Neolithic communities of southeastern Anatolia is entangled within a broader cosmological construct that includes the deposition of human remains in buildings, as seen with the skull building at Çayönü, and the construction of enclosures that had special ritual purposes, such as the case of Göbekli Tepe (see below).

In Anatolia, the importance of displaying decorated skulls in ritualized contexts is also recognizable in later Neolithic contexts (ca. 7000–6200 BC), as is the case of the recently discovered skull of an adult male, plastered and decorated with red ochre, which was found in an intramural tomb excavated at Çatalhöyük in central Anatolia and buried in the arms of a woman deposited in a pit that was part of the foundation of the house. The numerous layers of plaster and red paint that covered the skull have lead Hodder (2006: 149) to suggest that the plastered skull was circulated prior to its final burial. The skull has been interpreted as the head of a person of prestige status (e.g., a sort of shaman) that was displayed and buried in this particular manner, within the foundation of a new house, in the process of creating genealogies for the people inhabiting the house.

Such examples can help illustrate that the fragmentation of the body served the purpose of embodying the memory of the dead among the living and strengthen the relationship between ancestors and the community of the living. In this way, the body could be transformed into an object useful for materializing the memory of ancestors among the society of the living. This aspect of material religion in the Near East can be seen in other archaeological contexts in which the display and use of body relics are important elements for constructing community identities (as, e.g., with the Early Bronze Age II, ca. 2900–2350 BC, "body libraries" found in charnel houses at Bab edh-Dhra in Jordan, Chesson 2007).

In general the fragmentation and display of parts of the body in public might have occurred to emphasize commonality versus individual personhood when cooperation was needed or in instances of radical transformation of the social and economic organization that could have increased the level of stress among the community's members.

Animism and the First Ceremonial Buildings at Göbekli Tepe (Southeastern Turkey)

The importance of creating a sense of community through ritual and religious practices is clearly evident when confronting other Neolithic contexts in the Near East, such as with the extraordinary ceremonial architecture unearthed at sites like Göbekli Tepe and Nevali Çori in southeastern Turkey that dates to the Pre-pottery Neolithic (ca. 9500–7000 BC).

In particular, the numerous stone enclosures from both the PPNA level III and the PPNB level II at Göbekli Tepe have been interpreted as the first examples of religious architecture associated with forms of animism during a phase in which the urge to create a sense of community appears pivotal for a society that was transforming toward new subsistence strategies associated with farming (Dietrich and Notroff 2015). Such an interpretation is based on the actual presence of large, almost underground, circular buildings but most of all by the presence of a unique iconography based on centrally located, tall,

T-shaped stelae with clear evidence of stylized anthropomorphism and a series of bas-reliefs representing elements of wild animals in movement. This mixture of animal and stylized human representation has led to a discussion on the possibility that the enclosures represent locales of spiritual representation of the encounters between the human and natural domains, probably in connection with a belief in the supernatural world.

Within this unique ritualistic context, Busacca (2017: 2) adeptly argues that the Pre-Pottery Neolithic examples of religious/ritual architecture of Göbekli Tepe represent "precise techniques of visual representation aimed to create illusions of motion and the intentional arrangement of depictions within the ritual space that contributed to the performative 'animation' of the animal image and to a ritualized *encounter* between humans and animals."

Increasing Social Complexity: From Community-Oriented Ceremonial Buildings to the First Temples

At the end of the Neolithic, the transformed communities of the Near East were fully established in an agropastoral economic subsistence strategy; their increasing size brought about a constant need for a greater level of agropastoral production and the establishment of larger centers in which specialized activities (e.g., metal and pottery making, textile production, etc.) were controlled by emerging elites. It is within this socioeconomic landscape that a more organized sense of both the world of the dead and the relationship with the supernatural domains emerged among ancient Near Eastern communities of the Chalcolithic period (i.e., fifth and fourth millennium BC, Hole 1983).

Regarding funerary customs, this trend is clearly evident in the creation of areas dedicated to the deposition of the dead in large cemeteries. For example, at the end of the fifth millennium BC (i.e., the Ubaid period), large cemeteries were created outside of the most important centers of southern Iraq and southwestern Iran (e.g., at Eridu, Ur, and Susa) as well as in areas not directly interconnected with settlements and considered as possible cemeteries for nomadic groups (Pollock 1999: 104–204). The interments are mostly of single individuals positioned on their backs, with the skeleton in an intact articulated status, and accompanied by a few items of funerary goods (e.g., pottery vessels, beads, stone mace-heads, clay figurines, etc.). In southern Iraq little or no status differentiations are recognizable in the funerary goods, whereas in the cemetery of the southwestern settlement of Susa (ca. 4200–3800 BC), rich furnishing goods including copper objects (e.g., axes, disks, needles) and elaborately decorated vessels were discovered in the graves of specific individuals in which some fragmented skeletons were also found, to suggest either a secondary deposit or death at war (Hole 1983, 1989). In some circumstances the graves were empty as a consequence of their possible use as cenotaphs or ritualized tombs. According to the French archeologists Morgan and Mecquenem, who excavated the site at the beginning of the twentieth century, there was a link between the large cemetery (with more than 2000 graves) and the massive platforms (i.e., the low platform, *massif funéraire*, and the stepped platform, *haute terrasse*, Hole 1983: 316–317). Hole (1983: 315) has suggested that it is at this specific southwestern Iranian site that we can signal the first correlates of an "increasing institutionalization of religion" in which control over production starts to be centered in the hands of a small community of priests representing about 3% of the population, taking into account the differences in funerary goods within the extramural cemeteries. This interpretation is based on the increasing complexity in burial data, the complexity of the decorative motifs (human, animalistic, and geometric) depicted on the vessels, the creation of anthropomorphic figures, the presence of the monumental, 10-m high stepped platform of unbaked mud bricks with the possible presence of a temple on top (that was burnt at the end of its use) within the 15-ha village, as well as the iconography engraved on the seals (e.g., the so-called master of the animals or stepped platforms) at Susa during the late fifth millennium BC (Pollock 1999: 176). Interestingly seals are never

found in funerary contexts, whereas some objects depicted in the image engraved on the seal (e.g., the beakers) are represented as part of the funerary goods found in the graves, thus suggesting that the seals were not associated with individuals but rather "they symbolized or depicted rites and institutions" and served the purpose of marking "goods that were brought to the temple for use in the rites depicted or for the shrines of particular deities" (Hole 1983: 321). Within this perspective, Rothman (2004: 102) adds that the case of Susa "demonstrates how religious ideology, the mobilization of labor in the service of god and community, and the use of pottery style and mortuary behavior to signify new statuses and reward political allies combined to catalyze growth, functional segregation, and the development of leadership in Susiana."

Thus, the presence of larger buildings in a more complex urban fabric of newly founded centers in ancient Mesopotamia and Iran represents both a new sense of centralized authority, as well as the need for representing a link with the spiritual domain. This element will further emerge during the fourth millennium BC, when the presence of large buildings with a central courtyard (*mittelsat*) or tripartite plan most probably dedicated to religious practices and built on high terraces or large platforms becomes more common in large- and medium-sized urban centers. In particular, the construction of buildings with a tripartite plan appears to have been derived from plans of private houses typical of the Chalcolithic period. Within this perspective, it is interesting to notice that in Sumerian the word for "house" is *é*, for temple is *é-name of the divinity* or the cosmological locale associated with the divinity, and for palace is *é-gal* ("the great house") testifying to the central role played by the institution of the extended family in the construction of Mesopotamian society.

Housing the Gods in Mesopotamia: The Fourth Millennium BC Sacred Precincts of Anu and Eanna at Uruk

The evolution of the first temple built on a high terrace is clearly recognizable at the site of Eridu in southern Iraq, where a series of layers testify to the transformation from a one-cell building into a tripartite building between the end of the fifth and end of the fourth millennia BC. However, clearly the most famous examples of Mesopotamian religious architecture during this period are the Anu and Eanna precincts in the large mid-to-late fourth millennium city of Uruk in southern Mesopotamia (levels VI–IV). In particular, the Anu precinct was composed of a small stone temple at the bottom of a high terrace (ca. 16-m tall) in which a tripartite temple, most probably dedicated to the Sumerian god of heaven, Anu, was located and reachable by a long staircase, whereas the Eanna precinct, dedicated to the goddess of love and fertility, Inanna, was composed of a series of buildings located on a 10-m high terrace, which included large outdoor spaces, halls, and buildings with a tripartite plan (Heinz 2012: 179–185). The lack of large indoor spaces within these primeval religious buildings at Uruk has suggested to D'Altroy (2001: 463) that during the second half of the fourth millennium BC, Uruk's religious practices were "spatially and socially exclusionary … and performance-oriented rather than participatory." In fact, in part due to climate conditions, it appears that the use of outdoor spaces for the performance of rituals and the public display of power gained by the religious elites was a common religious practice in the Near Eastern tradition. Furthermore, as noticed starting with the large stepped platform at Susa, the visibility of monumental religious buildings from afar becomes a priority of Uruk's elites, which was further emphasized by their highly decorated facades that were adorned with either wall paintings or colorful stone and clay cones embedded in the outer walls to create a sort of proto-mosaic effect. In so doing, religious monuments were built in order to impress not only the entire urban community but also the people arriving at this large urban center (ca. 250 ha in extension at the beginning of the third millennium BC) through "a visual statement of power" (Pollock 1999: 178).

Within this context, the figure of a political/religious leader (i.e., the so-called king-priest) is part of an innovative iconography typical of the late Uruk period (i.e., late fourth millennium BC).

He is usually portrayed standing with a beard and clothed in a rounded hat and net skirt and sometimes bearing weapons while confronting enemies, hunting, or offering tributes. This figure was also probably represented in the missing part of the famous meter-high Uruk alabaster vase, in which the natural world (represented at the bottom with water, plants, and flocks of animal) is linked with the procession of naked humans bestowing offerings to a goddess (most probably Inanna) in the upper section of the vase (Pollock 1999: 189–190, Fig. 7.7). The scenes depicted on the vessel are part of the hierarchical Mesopotamian system in which gods and goddesses represent different aspects of nature and mankind and their earthly representative, i.e., the king-priest, is given their consent to control and dominate nature owing to his pious devotion to them.

Thus, at the end of the fourth millennium BC, religious beliefs and practices in Mesopotamia are clearly entangled with politics and economics. Starting from this historical moment, it becomes clear that these three dimensions cannot be easily separated from each other and that the possibility of distinguishing secular and religious perspectives in the life of Near Eastern pre-modern societies becomes a very complex exercise for interested scholars (Fowles 2013: 4–12).

Despite such a complex system of religious beliefs and practices, the archaeological data associated with funerary customs dating to the end of the fourth millennium BC in Mesopotamia does not exhibit a similar level of complexity. However, further north, in the Caucasus, northwestern Iran, and eastern Anatolia, as well as in the Levant, the archaeological data related to funerary customs allows us to reconstruct a more complex scenario. It is especially in the northern regions that a burial tradition emerges as unique and further marks the funerary customs of the people inhabiting such a broad region. An example is the custom of burying individuals in large funerary tumuli (i.e., the *kurgan*, a Russian word for burial mound or tumulus), a funerary custom that began in the Pontic region and then becomes a typical funerary architecture used in the southern Caucasus regions, eastern Anatolia, as well as northwestern Iran starting from the fourth millennium BC.

A New Picture of the Cosmic World

At the end of the fourth and beginning of the third millennia BCE, a dramatic transformation occurs in Mesopotamia and its peripheral regions due to the collapse of the broad commercial networks established by southern Mesopotamian elites in various Near Eastern regions. It is during this period that changes in funerary customs and religious practices occur. In general, the presence of large extramural cemeteries with a clear variability in grave architecture and funerary goods emerges as a distinctive trait within numerous Near Eastern regions.

Due to the increasing presence of written documents in ancient Mesopotamia, the third millennium BCE represents a distinctive period in which the description of funerary rituals as well as forms of religious beliefs and practices allow for clearer reconstructions.

In particular, the organization of the Sumerian pantheon mirrors the social organization of Mesopotamian societies with its numerous city-states and gods, some of which are patron deities to specific cities (See Pollock 1999 (Table 7.2) for a list of the most important Sumerian gods, their attributes, and their referring city). The pantheon is organized in an "extended" familial type of scheme in which the sovereign god of the heaven, Anu, is the father of the god of the storm (Enlil), of the fresh water (Enki), and of mother earth (Ninhursag), from which all the other Mesopotamian gods and goddesses have been generated (Bottéro 2001).

In the Sumerian tradition, the cosmology was initially envisioned with a strict horizontal division between the realm of the living and the netherworld originally located in the mountains to the east; slowly, this separation became vertical with a separation between the "Great Above" (where the celestial gods were located), the world of the fresh water (Abzu/Apsu) (where Enki is in charge), and the netherworld commanded by the queen of the netherworld (the goddess Ereshkigal) and her companion (Nergal). As accurately pointed out by Pongratz-Leisten (2013: 40), "the direct and unbreakable link between the heavens and the lower realms was guaranteed by the cosmic

mooring rope that bound the two hemispheres together" in which "cities and temples can be seen as the physical location where these two spheres were held together by the cosmic bonds, as is Nippur with the Enlil Temple and later Babylon with the Temple of Marduk."

While each city was represented by its temple and the patron god that was venerated in it, other temples were also present within the city, as seen with the city-state of Lagash and the reference to its 20 temples in third millennium BCE texts (Pollock 1999: 186). The temple slowly became the center of Mesopotamian city-states; this phenomenon is recognizable in the symbols associated with the different cities in the so-called city sealings of the Early Dynastic I period (2900–2750 BC), in which an altar was associated with the emblem of the city (e.g., "sun for Larsa," Postgate 1992: 109). Due to its importance, the temple was usually located at the center of the city and, in some circumstances, built on top of a terrace through the means of stepped towers (i.e., the *ziqqurat*), reminiscent of the stepped platforms built at Susa and Uruk between the end fifth and throughout the fourth millennia BC, and slowly became the quintessential marker of Mesopotamian religious architecture.

Moreover, in Mesopotamian cities Early Dynastic temples (2900–2350 BC) could be distinguished by those embedded in the urban fabric and those built on high terraces or else as those representing institutional religious buildings and those associated with more domestic religious practices. This is clearly evident in important centers such as Khafajah (levels VII–VIII) in the Diyala (Iraq), where there was a distinction between institutionalized religious buildings, as in the case of the Temple Oval that represented the tradition of the shrine built on top of a high terrace, along with the Sin Temple, a "low" temple with a monumental entrance, large open courtyard, a series of annexed rooms, and a long cella room with a bent-axis entrance, in contrast to other low and smaller temples (e.g., the Small Temple, Heinz 2012: 188) built in a different section of the city and embedded in a nonpublic urban fabric that might have served the purpose of "popular religion" (i.e., the religion of "common" people, Pollock 1999: 192).

More generally, Mesopotamian temples had an altar along the short wall that was visible after a 90° turn from the entrance to the room, and, presumably, the image of the venerated divine figure would have been located either on top of the altar or along the wall behind it. According to the texts, the statues were probably composed of different materials with a central part comprised of wood or stone, with gold and other semiprecious stones used to decorate the body. The statue representing the divine figure had a proper life. This religious practice of giving life to votive statues of gods and goddess through the "opening of the mouth" ritual is peculiar to the ancient Near East and Egypt. In fact, as summarized by Pollock (1999: 187), in ancient Mesopotamia, "the statue underwent mouth- and eye-opening rituals in order to animate it. After these rituals were performed, it was clothed in luxurious garments and jewelry, fed, and brought into the temple, where it was placed on a pedestal in the inner sanctaury." At the end of their "lives," the statues were dismantled, and the remaining parts are occasionally found in archaeological contexts (as seen, e.g., in Ebla and Mari during the third millennium BC). Within this perspective, even the architecture and ritual paraphernalia associated with the religious buildings went through a process of ritual termination and required a proper burial similar to the one granted to human beings. Including the famous Early Dynastic figurines of devotees represented with wide open eye, arms attached to the body, and hands either joined together or holding a cup.

As mentioned before, since its first appearance during the Late Chalcolithic period, the temple functioned not merely as a center for religious activities but rather as a complex administrative structure in which, beginning from the third millennium BC, the presence of archives with cuneiform written texts documents an established control over economic activities by the religious authorities, from the production and exchange of goods to the organization of labor (Postgate 1992: 109–136). While it was originally thought that the Mesopotamian cities primarily functioned as "city temples," the important role played by the palaces and rulers in controlling the administration of the cities has more recently been defined.

When moving outside of proper Mesopotamia, it is clear that the temple had a different political role; in fact, it usually consisted of a building with one single room and was smaller as compared to the large religious institutional complexes built in southern Mesopotamia city-states. In these contexts the presence of large funerary complexes unearthed in western Syria and southeastern Turkey is of great interest (such as those unearthed at Tell Banat, Gre Virike, and Umm el-Marra) as testimonials to the growing concern for offering tributes to elite ancestors, probably in order to connect the newly emerging royal genealogies with the cosmic dimension in a context where the process of urbanization arrived as a consequence of the urban revolution in southern Mesopotamia (Schwartz 2012).

The Search for Immortality by the Mesopotamian Rulers

According to the Sumerian King List, copies of which are available from early second millennium BC cuneiform texts, Mesopotamian kingship descended from heaven, and the ruler was thus the vicar of the gods on earth, thereby making it impossible for him to reach a god-like status as was the case with neighboring Egypt. Despite this information, additional textual evidence clearly testifies to the interest in achieving the immortality by the Mesopotamian leaders as described in tablets narrating the epic stories of Gilgamesh or other mythological stories associated with this subject, such as the descent of the goddess Inanna/Ishtar to the netherworld and the myth of Adapa. Life, death, the netherworld, and the search for immortality are elements linked not only to Mesopotamian mythological stories but also to other ancient Near Eastern societies.

Among these stories, the one narrating the relationship between Inanna, the goddess of fertility and love, and the shepherd, Dumuzi, perhaps most clearly illustrates this struggle for immortality as well as the connection between the netherworld, the celestial world, and the desire to wield control over nature for agropastoral economic subsistence strategies. According to the story, after their marriage Dumuzi substitutes the goddess Inanna in the netherworld, who had previously decided to descend to the netherworld and was kept there by her sister Ereshkigal; however, after 6 months below ground, Dumuzi was allowed to leave the netherworld and was substituted by his sister Geshtinanna, who is also the goddess of the grape and wine, thereby allowing Dumuzi to return to his job as a shepherd and oversee the grazing of the animals (Jacobsen 1976: 27–73). Another mythological story in which a mythological Mesopotamian king struggles with his desire to reach immortality is the one narrated in the 12th tablet of the Epic of Gilgamesh (i.e., Gilgamesh and the Netherworld) in which the king of Uruk, due to the death of his friend Enkidu, decided to travel into the netherworld in search of immortality but instead learns at the end of his journey that the fate of humans is in the hands of the gods. While the obvious intention of these mythological stories is to narrate and explain the way nature functions (e.g., the agricultural cycle, the end of human life), a secondary function is to also represent the struggle of the Mesopotamian rulers to become immortal through divinization (Pollock 1999: 187–188).

Regarding the actual divinization of kings, at the end of the Early Dynastic period, after a period marked by the regionalization of power divided among city-states, we encounter the advent of the first territorial empire (i.e., the Akkadian period) and starting with king Naram-Sin (2254–2218 BC) and the first attempt by a Mesopotamian king to reach divine status recognizable by the addition of the determinative for "god" before his name (Postgate 1992: 266–267).

The struggle of members of the elite to control the underworld and obtain a stronger connection with the cosmological order and divine world is evident in the increased complexity of funerary customs and the practice of lavish funerary rituals during the third millennium BC. In particular, during the third millennium BC, an increasing variability in the archaeological data associated with funerary practices is witnessed, as exemplified by the funerary remains discovered in Early Dynastic Mesopotamian contexts (2900–2350 BC). The importance of lavish

funerary rituals in ancient Mesopotamia is reinforced by written documents, such as the famous reform texts of Uru'inimgina, the last ruler of the First Dynasty of the city-state of Lagash (ca. 2400–2350 BC), in which details about the performance of the funerary rituals at this specific Mesopotamian city-state are described (Vogel 2012: 421).

The archaeological data from the Early Dynastic period greatly aid in reconstructing the funerary customs of ancient Mesopotamian communities, the quintessential example of which is the famous Royal Cemetery of Ur (2450–2350 BC, Woolley 1934; Zettler and Horne 1998). The cemetery was located at the bottom of the sacred area's temenos that was dedicated to the moon god, Nanna, and consisted of hundreds of graves with dates spanning the entire third millennium BC. Among them 16 royal graves were identified in which possible rulers of the First Dynasty of Ur were buried. These royal graves are comprised of larger than normal stone shaft graves with corbel or barrel vaults decorated with plaster and some traces of paint on the walls. The funerary chambers were located ca. 8–10 m in depth and reachable by a ramp; the associated bodies were usually wrapped in reed mats and placed inside a wood or clay coffin (Vogel 2012: 425). The funerary goods consisted of stone, metal and ceramic vessels, gold and semiprecious stone objects, highly decorated musical instruments, and, most notably, sacrificed individuals who accompanied the buried rulers (usually buried in dedicated "death pits") dressed with special clothing and jewels emulating those worn by the rulers. The ceremonies associated with the burial of the rulers must have been part of a theatrical performance that established the preeminence of the dynastic family over the netherworld as part of their cosmological connection with the world of the divine (Cohen 2005).

The importance of connecting royal genealogies with the divine is even more evident in the tradition of northern Mesopotamia and eastern Anatolia during the third millennium BC (Peltenburg 2013; Schwartz 2012). It is in fact in these contexts that archaeologists have found the earliest traces of human sacrifices associated with the disposal of individuals of elevated status (e.g., at Arslantepe and Bashur Höyük) during the beginning of the third millennium BC. As mentioned before, in this context the tribal form of social organization of the communities brought about the commemoration of ancestral figures through the construction of large funerary complexes (e.g., the White Monument at Tell Banat or the funerary complexes of Umm el-Marra and Gre Virike).

Moreover, it is at the western Syrian city-state of Ebla that both archaeological and textual evidences clearly document the important connection established by Syro-Mesopotamian communities of the third millennium BC between funerary customs and the creation of a cosmological world in which the royal ancestors were connected with the world of the divine. At this city-state a large mid-third millennium BC royal complex (i.e., the Royal Palace G) with an archive of thousands of cuneiform tablets written in a local version of Akkadian was brought to light by an Italian team of archaeologists (Matthiae 1995). In addition, underneath the palace a large shaft grave was discovered, and the royal funerary customs at Ebla are further enlightened by the tablets found in the archive that include the description of the ritual associated with the coronation of the new royal couple that was described as a pilgrimage of the couple from the temples dedicated to the local gods Kura and Barama in the city of Ebla to the mausoleum dedicated to the royal ancestors, i.e., the mausoleum in NE*nash*. In addition, within the Royal Palace G, the archaeologists discovered a standard representing two facing women, one seated and one standing, that can be interpreted as a material representation of a form of spiritual connection between the living queen and the ancestral seated queen who is dressed in special attire associated with the divine (Laneri 2016).

All of these elements are of extraordinary importance in providing a clear picture of the importance of the royal ancestors in continuing the royal genealogy, as well as the role of the ritual performance of the pilgrimage to the NE*nash* mausoleum as part of a religious practice that embedded the royal genealogy of Ebla within the cosmic world (Ristvet 2015: 87–89).

Meals for the Spirits of the Dead Ancestors

In reconstructing the evolution of ancestor worship in the Near East, some elements seem to be consistent throughout Mesopotamia, Anatolia, Syria, and Israel, such as the importance of caring for the dead through a proper burial and libations in the form of continual offerings of food and beverages postmortem, both of which are necessary for establishing and maintaining positive relationships between the living and the dead. In fact, in most ancient Near Eastern literature, the netherworld is described as a place with no lights where the "soul" of the dead (e.g., *gidim* in Sumerian) eats dust and mud and drinks wastewater; thus, the libations offered by the living are precious necessities that ensure the spirit of dead has a decent life in the netherworld (Vogel 2012: 429–431). Descriptions of how to properly care for the dead are outlined in numerous ancient written texts including the myth of Atrahasis, also known as the Babylonian flood story, or the death of Ur-Nammu (i.e., the first king of the Third Dynasty of Ur, end of the third millennium BC). Archaeologically, elements associated with offerings and libations can be identified by the presence of vessels that can be found among furnishing goods, as well as the remains of food within and outside the grave, and pipes and drains that connect the tomb dromos-entrance or the above floor with the grave room (Laneri 2016). In particular, the presence of residential graves planned and built within dwellings or palaces can indicate forms of caring for dead ancestors and a demonstration of the spiritual connection between the living and the spirits of the selected deceased (Laneri 2014).

More specifically, the tradition of burying select bodies representing dead ancestors in residential graves created inside of homes is a funerary custom that has characterized Mesopotamia since the beginning of the third millennium BC. Together with residential graves, the creation of areas specifically used for the sharing of meals with the ancestors on certain occasions is documented in third millennium BC texts, exemplified by cases such as the *ki.a.nag* (i.e., a funerary chapel) in the Sumerian cuneiform written tradition. The discovery of pipes and drains connecting the floor with the underlying funerary chamber, as exemplified by the case of the early second millennium BC residential graves excavated at the southern Mesopotamian city-state of Ur, confirms the custom of the ritual offering of libations to the buried dead by the living (Postgate 1992: 99).

Moreover, the offering of libations to the royal ancestors is mentioned in the previously mentioned texts from Ebla. Archaeologically speaking, the custom of venerating the memory of elite dead ancestors is recognizable at numerous sites including the royal mausoleum dedicated to the kings Shulgi and Amar-Sin of the Third Dynasty of Ur or the funerary complex of the Giparu dedicated to the *entu*-priestess of the moon god Nanna, both of which are built on the sacred *temenos* dedicated to Nanna in the city-state of Ur in the third millennium BC (Heinz 2012: 192–196, Fig. 9.5).

However, it is during the second and first millennia BC that tighter connections between funerary customs and religious practices associated with the care of dead ancestors become widespread in Near Eastern communities. In particular, the performance of a ritual associated with the caring for dead ancestors had a specific Akkadian term, i.e., *kispu*, and represented a feast in which a meal is consumed as a dedication to the memory of the ancestors (Tsukimoto 2010). Starting from the second millennium BC, the performance of the *kispu* ritual occurred at specific locales called the *bit kispi*, which is "the building of food and drink offerings to the dead" (Al-Khalesi 1977: 57).

Numerous attempts have been made to identify this type of locale in the archaeological record. Even though such an investigation is complex by nature, the discovery of a large shaft grave under the royal palace of Qatna in western Syria is a great opportunity to envision how the cult of the ancestors might have been performed and how the *kispu* ritual was performed. In fact, the excellent state of preservation of the grave excavated by a team of Syro-German archaeologists (Pfälzner 2012) illustrates the potential for archaeology to

be used as a tool in reconstructing the agency of ancient communities (Laneri 2016).

A royal palace and its related hypogeum were also brought to light at this western Syrian center. The palatial complex's long chronology dates from the eighteenth to fourteenth centuries BC, at which time the palace was destroyed by either the Hittites or their enemies during the reign of Suppiluliuma I. The funerary chambers of the hypogeum were located about 12-m below the palace's foundations and were connected to the palace through a long, stepped corridor. The corridor contained four wooden doors that led to the antechamber, reachable by disposable wooden ladders, and served as the entrance to the hypogeum (Pfälzner 2012).

The entrance to the rock-cut hypogeum consisted of a large gate flanked by the presence of two basalt statues of seated royal male figures with offering bowls in front of them. Examples of similar stone statues can be found in other Syro-Hittite contexts and have usually been interpreted as associated with the *kispu* ritual dedicated to memorialize the royal ancestors (Bonatz 2016). From the antechamber, a door led into the main large funerary chamber that was columned and gave access to three smaller rooms located on each side. The grave had multiple depositions representing at least the last 50 years of the palace's use. In fact, together with more than 2000 objects and funerary goods (i.e., numerous ceramic vessels, gold or semiprecious stone beads, decorative plaques, miniature vessels, a modeled hand of gold, an extraordinary example of an amber lion), the remains of a total of about 20–24 individuals were found. From among the skeletal remains, only in one case was the skeleton discovered in a fully articulated position. In the central chamber, a basalt sarcophagus and four wooden biers were used to contain the bodies of the deceased.

The presence of benches, vessels, and animal bones in this room supports the hypothesis that it was used as a sort of "banqueting room" for performing the *kispu* ritual in remembrance of the royal ancestors that, as noticed since the case of Ebla, were of fundamental importance for strengthening family ties as well as the political, economic, and religious leadership of the new royal individuals (Laneri 2016). The importance of the cult of the ancestors is especially evident among the Amorites, who have characterized the ethnic identity of western Syria and later of southern Mesopotamia and the Levant since the end of third millennium BC (Burke 2011). Their presence in this broad region has also marked dynastic lineages (as is the case of the first Babylonian dynasty of Hammurabi I) as well as religious traditions that also continue during the first millennium BC (e.g., the in antis temple).

The Materialization of Spirits

It is during this period that the performance of ritual practices established the materialization of profound religious beliefs that come to mark the religiosity of Near Eastern communities throughout the second and first millennia BC. This is the case of the *akitu* festival, which celebrates the beginning of the New Year. Even though the tradition of the *akitu* festival has origins that can be traced back to the third millennium BC, it is during the second and first millennia BC in Babylonia that the festival becomes "the most complete expression of Mesopotamian religiosity" (Frankfort 1978: 313). The feast was established through the enactment of a 12-day festival celebrating the victory of the primary Babylonian god Marduk over Tiamat that embodied primordial chaos. More specifically, the festivals celebrated the relationship between the god Marduk and the king through a ritualized journey of the statue of the god by the king and the high priest from the temple of Marduk in Babylon (i.e., the *E-sagila*) and the *bit akiti* located outside of the city and by the narration of a series of mythological stories, including the creation of the world, the *Enuma Elish*. Moreover, through the millennia, the *akitu* festival became the quintessential Mesopotamian religious feast to celebrate the spring season, but, most of all, it "was a political device employed by the monarchy and/or the central priesthood to ensure the supremacy of the king, the national god, and his capital city" (Bidmead 2014: 2).

Moreover, it is starting with the second half of the second millennium BC that exchanges of products and ideas crossed the traditional frontiers of the ancient Near East. This historical phase is in fact known as the "International" period. Extensive Egyptian and Hittite archives record in cuneiform writing the exchange of goods and forms of alliances between the rulers of the "great powers" (i.e., the Egyptians, Hittite, Babylonians, and Assyrians), providing a testimonial to the development of intense commercial exchanges, new forms of artistic production, and forms of syncretism in the religious beliefs of the involved communities. Of special interest during this period is the entanglement between spirits and stone reliefs in Anatolia. In this geographical context, the relationship between natural phenomena, the belief in spirits, and their representation on stone reliefs is recognizable since prehistoric times, but it is specifically during the Hittite kingdom that this form of material religiosity becomes pivotal for Anatolian communities. Of particular interest is the open-air sanctuary of Yazilikaya (ca. 1400–1300 BC) near the Hittite capital of Hattusa in central Anatolia. The sanctuary was connected to Temple I of the storm god Teshup in the capital through a long trail and was conceived as religious architecture incorporating natural rock caves in which a series of bas-reliefs were engraved in the natural bedrock (Matthiae 1997: 68–73). Depicted in the first room (Room A) of the open-air sanctuary is a parade of gods, on one side, and goddesses, on the other side, coming toward each other from opposite sides of the room. The divine figures are represented standing on top of animal and human figures. The parade terminates with the meeting of the two primary Hittite divine figures, the storm god, Teshup, who wields his mace, and the goddess of the sun, Arinna. In Room B, the representation depicted on a large bas-relief is dedicated to the memorialization of the spirit of the dead king Tudkhalia IV, who is shown wearing the clothing of a priest and being embraced by his protective god Sharruma, who introduces him to the netherworld. The name of the king is engraved in the Hittite hieroglyphs cartouche next to head of the god.

The end of this period (i.e., the Late Bronze Age) is a transformative moment in the history of the Near East marked by the collapse of numerous kingdoms located in western regions (e.g., the Hittite kingdom) due to the arrival of the "Sea People" from the Mediterranean region during the twelfth century BC. At the end of this historical phase, a transformed and fragmented political landscape emerges, and as a consequence the Syro-Hittite city-states of western Syrian and southeastern Anatolia region become the new cultural and political venues of local tribal domains. It is within this context that stone bas-reliefs located in outdoor spaces, depicting ritual and religious visual representations, became a fundamental part of the performance of religious practices by elite members of the community (Gilibert 2011).

The tradition of using stone bas-reliefs as a medium for symbolically containing the souls of the dead encounters in the royal Hittite funerary continues into the end of the second and the beginning of the first millennia BC, when depictions of the deceased on stelai as well as written texts associated with iconographic representations appear to substitute the physical presence of residential graves within private dwellings or palaces of the Syro-Hittite city-states. This is, for example, the case of the stone stele of Katumuwa, a non-elite citizen of the eighth century BC city-state of Sam'al/Zincirli in southeastern Turkey that was found in a room of a private dwelling not associated with a grave. In the stone bas-relief, the deceased is depicted in front of a banquet table, and it is possible to infer from the written inscription in Aramean that "the soul was expected to dwell on in the stele in order to enable the deceased's participation in the offering meal" to the gods (Bonatz 2016: 187).

In addition, the tradition of embedding the cult of the souls of the ancestors into decorated slabs (i.e., orthostates) becomes pivotal for the religious practices associated with the memory of the royal ancestors, also among the Assyrian kings during the first millennium BC, when Assyria rises from northern Mesopotamia (i.e., along the Tigris river) to become the first universal empire in human history. This is especially the case of the

orthostates representing the tree of life with two specular genies in one room. According to Richardson (1999/2001), the tree of life represents the spirits of dead kings who were to be buried in the Old Palace at Assur, the first palace of the Assyrian capital dating to the early second millennium BC. According to the Assyrian kings, the palace at Assur is the "palace of repose, the eternal abode," and in fact, it is in the southeastern section of the palace that a series of underground funerary chambers with stone sarcophagi bearing inscriptions of the Assyrian rulers were found. Of great interest is the fact that after the construction of the new palace complex of Ashurnasirpal II (883–859 BC) in the new capital of Nimrud/Kalhu, the queens started to be buried in an underground funerary complex located in the southeastern corner of the palace (Lundström 2012).

Thus, the northwestern palace of Nimrud might have had the function of becoming the locale for connecting with the ancestral spirits of past Assyrian rulers through their embodiment in the orthostates, while the spirit of the queens instead rested in the domestic section of the palace as a symbol of their connection with the future rulers of the Assyrian empire.

In addition, according to Harmanşah (2015: 126), the anthropomorphic representation of the god Ninurta (i.e., a leading god in the Assyrian pantheon and to whom Ashurnasirpal II dedicated a temple and a ziqqurat in the new capital of Nimrud) functioned "as a conceptual metaphor for the image of the king, whose duty was to restore order in the world." In order to achieve this duty, Near Eastern kings performed festivals and rituals both inside and outside of the city walls with the purpose of both connecting the royal genealogies to the divine world as well as displaying to the communities the pious and civilizing role of the ruler. Through the performance of festivals and the creation of commemorative and religious monuments, it was possible for Near Eastern rulers to intertwine ritual practices with political propaganda in (ibid. 135) "ceremonial events that brought together the king, the dynastic family, the army, state officials, citizens, gods of the city, and ancestors all at the same time" in Mesopotamian as well as Syro-Hittite cities.

The Origin of the Migdol Temple in the Levant

During the second half of the second millennium BC, activities of economic and cultural exchange are primarily concentrated in the western regions of the Near East. During this period elements of commonality in both religious and funerary customs practiced by the communities inhabiting these regions also emerge, such as with the use of specific types of religious architecture, i.e., the long in antis temple, which links western Syria and the Levant during the second and especially the first millennium BC. The typical architectural plan of the in antis temple is of a single-roomed temple with thick walls, suggesting the hypothesis of a multistoried structure protruding toward the entrance in order to form either an antechamber (in same cases with corner towers) or two flanking sides to the entrance; in the back, a large room (either long or large) with a niche embedded in the back wall represents the religious cella where the statue of the god was most probably located (Burke 2011: Fig. 55.1). In some circumstances the cella presents two rows of columns in the main room that act as supports for the roof and divide the cella (see, e.g., the double temple dedicated to Ba'al and Astarte at the Late Bronze Age site of Emar along the middle Euphrates river in Syria, Matthiae 1997: 116).

Examples of *antentemple* coming from third millennium BC Syria are reminiscent of this type of temple. From the site of Ebla, further examples dating to the third millennium BC are available from the archaeological record and especially moving into the beginning of the second millennium as seen with the in antis temple dedicated to Ishtar, the goddess of love and fertility (corresponding to the Sumerian Inanna). This temple can be considered as the standard for religious architecture and later evolves into an established tradition during the first millennium in Syro-Hittite and Aramean city-states, such as Ayn Dara, Aleppo, and Shechem, as well as other centers located in western Syria and also Canaanite contexts in the Levant (Matthiae 1997: 182–191).

Particularly in the Levant, the tradition of the single-room shrine, sometimes with towers flanking the entrance (the *Migdol* Temple of the

Bible), becomes popular. The development can be traced to contacts between different ethnic identities in the region (i.e., Canaanites, Phoenicians, Israelites, Philistines, etc.) and especially the popularity of western Syrian religious cults of gods like Ba'al, Dagon, and Astarte, whose presence in the region is also legitimized by iconographic representations. Obviously this type of temple brings to mind the description in the Old Testament of the first Israelite temple built in Jerusalem by Solomon during the tenth century BC (1 Kings 6:1). The detailed description of its construction in the Old Testament suggests that the workforce and building materials needed to construct the temple were brought to Jerusalem from numerous Canaanite and Phoenician city-states (e.g., from King Hiram I of Tyre), further strengthening the links between these different communities and suggesting syncretic forms of religiosity that are also confirmed in the stories narrated in the Hebrew Bible (Burke 2011: 898–901).

In the Name of One God: The Creation of the Bible and Funerary Customs in the Levant

The first millennium BC has been considered by Karl Jaspers as the Axial Age, signifying the simultaneous appearance of new forms of spirituality in multiple parts of the world based on spiritual interiorization as well as monotheistic religious beliefs. In the Near East, this period is marked by the formation of the first universal empires (i.e., Assyrian, Babylonian, and Achaemenid empires) and the emergence of new forms of religious behavior and experiences: the first form of monotheism by the Israelites in the Levant (i.e., Judaism) and a deepened interiorization of religious spirituality within other Near Eastern communities (e.g., Iran and Babylonia).

These new developments occurred as part of a lengthy process that did not end in a few years or even a few decades but rather lasted for centuries, allowing the different Near Eastern societies and their associated religions to be exposed to phenomena of cultural osmosis as well as antagonism against attempts of cultural colonization. This aspect is especially evident when forms of imperial power eradicated communities from their local contexts, as seen in the case of the Assyrian and Babylonian empires.

Within this complex sociopolitical landscape, the case of the Levant is emblematic with its fragmented political identity during the end of the Late Bronze Age and beginning of the Iron Age when the whole region was comprised of different communities (e.g., the Canaanites, the Israelites, the Philistines) and diverse forms of religious practices and funerary customs. Starting with the military conquest by first the Assyrians, and later the Babylonians, we witness the development of a stronger affinity toward the cult of one god, i.e., Yahweh, as evidenced by the one dedicated temple erected in Jerusalem by Solomon and as documented in the written rules of the Torah.

In terms of funerary customs, until the sixth century BC, the funerary tradition of Levantine communities is based on the use of cave, chamber, and bench tombs cut into the natural bedrock. In some instances these tombs could be elaborated with a decorated entrance as seen in the case of tombs of high officials of the kingdom of Judah in the famous Silwan cemetery (ninth to seventh centuries BC) located just across from the city of Jerusalem (Bloch-Smith 1992). In a way similar to the royal hypogeum of Qatna, tombs of this context generally represented an eternal residence for the extended family "featuring a central room off which smaller chambers opened to accommodate individual family members," some of which were laid on benches (Burke 2011: 903).

As part of this religious process, even the cult of the ancestors, which as we have seen throughout this contribution has been pivotal to Near Eastern ancient communities, received a heavy reform by the Israelites through the words of the prophets. In fact, it is clear that the link between polytheism and the cult of the ancestors was part of a cultural and religious liaison with the Canaanites that was difficult for the Israelites to disentangle.

In particular, the Israelites believed in a netherworld that was not dissimilar to the one known from Ugaritic texts and thus belonging to the Canaanite tradition. In that tradition the god of

the netherworld is Mot, who according to a mythological story eats the main god Ba'al and, in order to free himself from the netherworld, uses Mot's brother as his substitute in a way that is similar to the relationship between the goddess of the underworld, Ereshkigal, and her celestial sister, Ishtar/Inanna, in the Mesopotamian poem narrating her descent to the netherworld. It is interesting to notice that in Hebrew the past tense of the verb to die is "mot" and the goddess of death in the western Syrian city of Emar is Shawal, not dissimilar to the divine figure controlling the netherworld in the Biblical tradition (i.e., She'ol). It is against such a religious tradition that the prophet Isaiah spoke (28: 15) when he criticized that the Israelites "have a covenant with Death (Mavet/Mot) and with She'ol we have made an agreement" (Hallote 2001: 110–114). In fact, it is in his book (Isa. 8: 19–20), which was most probably written during the Babylonian captivity of the sixth century BC, that the desire to dismantle this tight relationship with the Canaanite religious tradition emerges, especially regarding funerary customs.

Moreover, the complex, intertwined relationship between the Canaanites and the Israelites is clearly evident in Old Testament narrations about the construction of the first temple of Jerusalem by Solomon. As previously mentioned, it is unclear when the first temple of Jerusalem was erected, but it is important to further highlight that it was constructed according to an architectural template from the Canaanite tradition (i.e., the in antis single-room shrine) and that included among the people mentioned in the Bible that were involved by Solomon in its construction is a Phoenician king of Tyre, Hiram I.

In fact, one of the most extraordinary examples of sarcophagi, that of Ahiram I of Byblos, comes from an Iron Age Phoenician context. The sarcophagus is embellished with carved decorative motifs and iconography considered to be a quintessential representation of the cult of the royal ancestors in the Near East. The ruler is represented seated on a throne, flanked by a pair of winged sphinx, in front of a table holding offerings, with a procession of dancing and singing women lead by a priestess offering a lotus flower to the king; on top, the lid presents two male figures most probably representing the king with his son; along the lid, an inscription in Phoenician with 38 words describes the devotion of the son Ithobaal I toward his father Ahiram, the respectful manner in which the coffin should be treated, and the subsequent punishments that would ensue should anyone cause it damage, including the cancelation of "his registration concerning the libation tube of the memorial sacrifice" (Matthiae 1997: 233).

This representation is not dissimilar to those available from the previously mentioned Syro-Hittite stone stelai and confirms the fundamental role played by the ancestors in framing familial religiosity and cohesion in the entire Near East (Bonatz 2016).

Thus, it was a tremendous undertaking for the Israelites to also erase this aspect in the process of dematerializing the relationship with the supernatural domain and, especially, focusing the attention of devotees onto the words of god and not its representative power. However, the continuous violence suffered during the Assyrian and Babylonian invasions (including the destruction of the first temple by the armies of the Babylonian king Nebuchadnezzar in 587 BC) forced the Israelites to move toward a phenomenon of interiorization that was necessary to survive the struggle subsequent to these external invasions. Obviously, this phenomenon of interiorization also characterized other first millennium BC communities, and even among Mesopotamian societies, we encounter a higher value given to symbolic representation of the gods through the use of their astral symbol.

Thus, the beginning of monotheism in the Levant is part of a broader form of interconnection among people inhabiting such a broad region as well as a form of rejection of the violence that occurred with the territorial conquests of the first universal empires.

Conclusions

Even though the spirits of dead have been considered as the primeval step in the construction of human beliefs in supernatural beings, their role appears, both from archaeological and textual

evidences, as a founding pillar of the religious beliefs of the people inhabiting the ancient Near East from prehistoric periods until the first millennium BC. In particular, the continual revising of the memory of the dead ancestors through forms of calendric ritual practices has the power of cementing familial lineages and, at a royal level, to connect these lineages to cosmological genealogies.

It is for these purposes that also, starting with the Sumerians during the third millennium BC, the cosmos is envisioned following the parameters of the social organization of the city-states emerging within a fragmented regional power. In order to facilitate the connection with the celestial world, a "high temple" (i.e., the *ziqqurat*) became the focal point for the cult of the most important Mesopotamian gods.

For the rulers, a pious and a devoted life that exhibited respect to the ancestors and the gods was fundamental for gaining the respect of the members of the community. In order to reach this target, religious festivals and performances had to be properly enacted in dedicated outdoor spaces (usually in front of religious complexes) and well-built and maintained religious monuments.

Within this perspective, religious materiality was intensified by cognitive beliefs in supernatural beings, and traces of this materialization of religious beliefs are clearly evident in both public and domestic archaeological contexts. However, in the Levant during the first millennium BC, the need emerged for an interiorization of spiritual life without the assistance of external anthropomorphic figures that in ancient Mesopotamia were brought to life through the ceremony of the "opening the mouth" of the divine statues, as well as altars and temples for a daily connection with the divine. This will be a major turning point in the history of humanity with the creation of the Bible and of the first monotheistic temple that will later rise as a pivotal element in constructing the modern world.

Fung, Rosa

Lucy C. Salazar
Yale University, New Haven, CT, USA

Basic Biographical Information

Rosa Fung Pineda was born in 1935, the child of Chinese immigrants to Peru. Her childhood was spent in Casma, a rural town on the north-central Peruvian coast. She moved to Lima to attend secondary school and then went on to study at the Universidad Nacional Mayor de San Marcos (UNMSM), the largest and most prestigious public university in Peru and the center of the nation's archaeological and anthropological training and scholarship at that time. At the university, she specialized in Ethnology and Archaeology, receiving her bachelor degree in 1963 and her doctoral degree in 1967. The faculty at UNMSM featured major figures such as Luis Valcárcel, Jorge Muelle, Jose Matos Mar, and Raul Porras Barrenechea.

Fung remained at UNMSM throughout her career training generations of young archaeologists, and filling crucial administrative positions including director of the UNMSM Museum of Archaeology (1973–1978), coordinator of the Archaeology Program (1981–1984) and director of UNMSM's program of graduate studies in the Social Sciences (1985–1986). After retiring, Fung was appointed as emeritus professor in 1999.

Early in her career, Fung was married to US archaeologist, Edward P. Lanning, and the couple had two children, Eduardo, an engineer, and Zaida, a librarian and jeweler. Fung was a cosmopolitan scholar; she traveled to the United States and taught briefly at Arizona State University. Later in her career, she attended conferences and other academic activities in Chile, Brazil, and Japan.

Fieldwork

Despite limited research funds, Fung maintained an active career in the field, focusing most of her investigations on the Preceramic, Initial Period, and Early Horizon. Early in her career, she participated in the excavations directed by Seiichi Izumi in Chancay (1957) and Tumbes (1958). She eventually went on to direct her own investigations at Las Aldas, an Initial Period ceremonial complex on the Pacific shores of the Casma Valley (1963–1964); these served as the basis of her doctoral dissertation and first major monograph (Fung 1972). Over the following three decades that she worked at UNMSM, she organized and directed excavations at numerous archaeological sites along the coast and in the highlands. On the coast, her investigations at Chivateros (Fung 1968), Bermejo, Bandurria, Curayacu, and Chankillo were particularly important as were her excavations in the highlands at Pacopampa and Chavin de Huantar (Fung 1976, 1987).

Major Accomplishments

Rosa Fung was known for her rigorous and meticulous approach to archaeological science. She was a demanding professor and emphasized the importance of achieving a comprehensive knowledge of the literature in multiple languages and prioritizing the use of empirical data in the evaluation of competing hypotheses. At a time when Marxist theory dominated archaeology at UNMSM, Fung insisted on a theoretical approach that had its roots in Franz Boas, Alfred Kroeber, and John H. Rowe. She was scrupulous in her citations and avoided exaggerating the importance of her own findings. In the field, she lived austerely with a minimum of concern for her own personal comfort.

Fung was the first female to hold a position as a tenured archaeologist in the Division of Social Sciences in Peru and as such she was able to provide a refuge for female UNMSM archaeology students alienated by the misogynist attitudes that polluted the UNMSM academic environment in the 1970s.

Fung maintained a long-standing interest in fiber technology, including textiles and baskets,

an interest that was encouraged by her colleagues in the United States, such as Junius Bird. Given Peru's uniquely rich textile heritage and its remarkable preservation in the archaeological record, Fung's research and teaching in this area is particularly significant (Fung 1978). She thought that the textiles held the key to a better understanding of the development of complexity in the Andes.

While much of Fung's fieldwork produced results of lasting value, she is probably best known for her focus on Peru's north-central coast. In her synthetic overviews, she emphasized the crucial role of this region in the origin of civilization and the special place that Peru's rich marine resources played in this process (Fung 1972, 1987). Her salvage excavations at the Preceramic site of Bandurria, her pioneering description of the early Initial Period pottery from Tortugas (1972), her detailed analyses of the material culture of Las Aldas (Fung 1972), and her survey of the Casma Valley with her friend and collaborator architect Carlos Williams (Fung and Williams 1979) are all benchmarks in the literature on early Peruvian civilization.

Basic Biographical Information

Manuel Gamio Martinez was a Mexican archaeologist and anthropologist and a promoter of the welfare of indigenous Mexicans. He was born in Mexico City on March 2, 1883, and died on July 16, 1960, in the same city at age 77. Gamio completed his basic studies in the colleges Fournier and Colón and his high school studies in the National Preparatory School from which he graduated in 1903. Pressured by his father, he went to the School of Engineering but soon abandoned it due to lack of interest (Comas 1956; Gallegos 1996). In 1905, he obtained the post of Assistant in Evening Elementary School Supplemental Instruction No. 5, and in 1907, he joined as Editor of the Spanish section in the *Revista Moderna de México* (*Modern Mexico Magazine*) where he wrote about the Indians (Gallegos 1996: 25–65).

In 1906, he attended courses in archaeology at the National Museum taking classes on Nahuatl and ethnology given by Nicolas Leon and Andres Molina Enriquez. In 1907 he was appointed Assistant Professor of History class, and he presented, along with Leon, the project *Archaeological Guide to Mexico*, which was rejected. Being a student of the Museum, after an excursion to Zacatecas, his work "The archaeological monuments in the vicinity of Chalchihuites, Zacatecas" was published in *Anales del Museo Nacional* (Annals of the National Museum 3rd season, vol. II) (Gallegos 1996: 29–65). With the support of Zelia Nuttall, he studied at Columbia University with Franz Boas and Marshall Saville from 1909 to 1911. When he returned to Mexico, he was appointed Professor of Archaeology and Practice Professor of Archaeology in charge of the tours in the National Museum at the National Museum (August 1911–January 1912). In parallel, he became a Fellow at the International School of American Archaeology and Ethnology, and he was appointed Assistant Inspector of the Inspectorate of Monuments, which caused his dismissal from the Museum due to the neglect of his work (Gallegos 1996: 65–98). The constant duplication of work caused him problems with Franz Boas, who repeatedly complained about his informality with the International School. In June 1913, he quit the International School to take up the post of

C. Smith (ed.), *Encyclopedia of Global Archaeology*,
https://doi.org/10.1007/978-3-030-30018-0

Inspector in the General Inspectorate of Monuments. The following year he was appointed Head of Inspection, and he removed this office from the Museum (Gallegos 1996; Rutsch 2007).

Gamio held a number of important administrative positions throughout his career. He was member of the Supreme Council of Welfare from 1929 to 1932. In 1933, he held various positions in Public Education, National Economy, and the Agricultural Department. In 1934, he was General Director of Rural Population and Settlement in the Ministry of Agriculture and from 1935 to 1937 was a member of the Technical Advisory Committee of the SEP and, from 1938 to 1942, Head of Vital Statistics of the Ministry of Interior (Comas 1956: 12–17). In 1942, he was appointed Director of the Inter-American Indigenist Institute, which allowed him to join the indigenismo. He was reelected twice in this post, which he held until his death. One of his main concerns in the Institute was the improvement of indigenous peoples by the introduction of American soybeans in their diet (Comas 1956; Gallegos 1996).

Major Accomplishments

Gamio is sometimes considered to be the father of modern anthropological studies in Mexico. He postulated that anthropology should be considered as an applied science that focused on solving problems of contemporary peoples and on the cultural identification of indigenous cultures based on social, paleontological, archaeological, anthropological, linguistic, and historical knowledge (Gallegos 1996; Rutsch 2007). Gamio is also considered one of the key practitioners of stratigraphic excavation (Adams 1960). From 1910 to 1912, he excavated a series of deep trenches in the refuse deposits at San Miguel Amantla (Azcapotzalco) in Mexico City under the direction of Boas, who proposed the sequence of De los Cerros-Teotihuacan-Azteca for Mexico Basin (Gamio 1913).

In his classic work *Forjando Patria* (1916), Gamio portrayed contemporary Indians as backward, uneducated, and poor. He advocated stronger education programs, with an emphasis on Spanish education and the sciences. He saw cultural fusion, linguistic unification, and economic equilibrium as a means of building a new nation. His approach was launched in the new Department of Ethnographic and Archaeological Studies founded in 1917 (called also Department of Anthropology from 1919) in the Ministry of Agriculture and Development. As Director of the institution, he proposed regional studies as tools to understand and improve the indigenous population in their physical and cultural aspects and to exercise good governance. He proposed the use of applied anthropology as a tool of government, taking into account Molina Enriquez and Boas' proposals. With these concerns in mind, Gamio attended the Second International Congress of Eugenics in New York, representing the Mexican government (Urías 2002; López 2003).

Since 1917, Gamio conducted a regional study of the Teotihuacan Valley integrating archaeological, historical, and anthropological investigations. He held workshops to teach people Spanish; science and craft manufacturing, to encourage economic activity complementary to agriculture, were established (Gallegos 1999). The results were published in *The Population of the Teotihuacan Valley* (Gamio 1922).

When Gamio was appointed Assistant Secretary of Public Education, he moved the Department of Archaeology to the Secretariat (with the name of Department of Anthropology). He denounced the inflated expenses in several purchases of the Secretariat and had to leave the post and the country since Plutarco Elias Calles rejected all these allegations and supported the Secretary Puig Casauranc. With his departure, the Department was converted into an office for archaeological research (Department of Archaeology), canceling the second regional project in Monte Alban, Oaxaca (Urías 2002; López 2003). Gamio sought refuge in America. There he joined the archaeological-ethnographic exploration of the American Archaeological Society of Washington in Guatemala and then, sponsored by the Social Science Research Council and the Rockefeller Foundation Spelman, took the migration to the USA as subject of research, studying its impact on economy and society and the reasons

why migrants had preserved their traditions and customs without full integration to the American lifestyle (Gamio 1930, 1931).

Gamio never lost hope of regaining the confidence of President Calles and maintained a constant correspondence in which he always showed his unconditional support, despite the disdain of Mexican politics. He returned to the Mexican public administration occupying minor positions; this fact was the end of his archaeological career and also an impasse in his interest in improving indigenous races (Urías 2002: 110–113).

G

Garden Hunting

Peter W. Stahl
Department of Anthropology, University of Victoria, Victoria, BC, Canada

Introduction

Garden hunting was originally proposed as an indigenous subsistence strategy associated with pre-Hispanic tropical agroforestry in western Panama. At the time, it was offered as a potential means for farmers to supplement their carbohydrate-dominated diets in tropical environments that were traditionally viewed as "protein deserts" (Nigh and Nations 1980). As a subsistence option that exploited wild game animals that were either passively or intentionally attracted to indigenous agroecological landscapes, the possibilities of

garden hunting subsequently engaged the attention of archaeologists working in different areas of the world and biologists who were interested in its possible conservation implications within anthropogenic landscapes.

Definition

Garden hunting refers to subsistence exploitation of local animals that are attracted to the concentrated foraging opportunities provided in horticultural settings throughout the tropics. Although it refers to the opportunistic hunting of prey items whose availability in and around tropical gardens is increased simply as a by-product of farming, it is often used to connote the intentional game farming of anthropic (related to humans) faunas.

Historical Background

The term "garden hunting" was first introduced by Olga Linares (1976) to refer to a game procurement system less reminiscent of tropical forest hunting than of agricultural harvesting and maritime collecting. Previously, Conklin (1957: 102–103) had described a pattern of hunting in Philippine Hanunóo shifting gardens that was undertaken primarily for crop protection but also partly for food and sport. In particular, Linares (1976) inferred a pre-Columbian garden hunting pattern from preserved archaeofaunal specimens recovered at the site of Cerro Brujo which was occupied between CE 960 and CE 985 in northwestern Bocas del Toro province, Panama. The assemblage was overwhelmingly comprised of specimens identified as terrestrial mammals with strong predilections toward disturbed habitats and the increased foraging opportunities associated with swidden gardens. These included principally agouti (*Dasyprocta*), paca (*Cuniculus*), and armadillo (*Dasypus*), along with collared (*Tayassu*) and white-lipped (*Pecari*) peccaries, white-tailed (*Odocoileus*) and brocket (*Mazama*) deer, as well as rats (*Sigmodon, Oryzomys, Hoplomys*) and opossum (*Caluromys*, *Marmosa*). This "cultural faunal assemblage" differed markedly from fauna associated with "natural undisturbed habitats" as it was predominantly composed of disturbance taxa that readily invade anthropogenic clearing and excluded canopy-dwelling, shy, forest animals. The cultivation of root crops in tropical swidden gardens, which affects the locally available biomass of animals behaviorally preadapted to commensality, may have been a form of neotropical domestication in the manner of "animal tending." Garden hunting has become a popular strategy for understanding how indigenous agroecology can provide sufficient protein in tropical forest environments traditionally characterized as "protein deserts" (Nigh and Nations 1980) (Fig. 1).

Key Issues/Current Debates

The number of different kinds of species (richness) and their relative abundance (equitability) tend to be much higher in tropical forest ecosystems that have developed over longer periods of time under optimal growing conditions. Unlike temperate ecosystems which tend to be dominated by eurytopic taxa (generalists with broad niche requirements), tropical ecosystems contain more stenotopic taxa (specialists with narrow niche requirements). The latter have not had to adapt to extreme seasonal fluctuations, which enables them to increasingly partition their habitats and focus on environmental heterogeneity (Eldredge 1991). Tropical ecosystems composed of canopied forests are dominated by small-bodied animals which tend to be stenotopic as they perceive their environments in a relatively fine-grained manner. Many of their larger mammalian counterparts tend to be eurytopic as they exploit their temporally and spatially dispersed resources in a relatively coarse-grained manner and thus require greater foraging space (Mares and Willig 1994). Stable environments with low levels of resources tend to favor small populations with narrow niche tolerance and low reproduction rates. Small populations of K-selected (producing larger and/or fewer offspring less frequently) specialists can exploit heterogeneous environments that have reached maximum population levels

Garden Hunting, Fig. 1 Skinning a garden-hunted paca (*Cuniculus*) or hochi (San Calixto, Beni, Bolivia). (Photo by author)

more effectively. Stable environments with low resource levels tend to be characterized by many different kinds of species (high richness) with comparable population sizes (high equitability). This is in contrast to unstable environments with high and fluctuating resource levels which favor populations tolerant of broader niches and with high reproduction rates. Large populations of r-selected (producing smaller or more offspring more frequently) generalists are favored under conditions where the most food can be harvested and the largest families can be reared (MacArthur and Wilson 1967; Valentine 1971).

Environmental instability is important for understanding the historic evolution of biological diversity in the tropics. Although classical characterizations of tropical forest ecosystems have depicted a steady accumulation of species in benign settings over long periods of time, more recent models emphasize continuous but modest change as the engine behind high species richness. The ecological history of tropical forests is one of dynamic stability, which relies on temporally and spatially localized instability to prevent monopolization by a few species while presenting new opportunities for others (Connell 1978; Colinvaux 2001). Sporadic and localized instability in canopied forests may be caused by a variety of natural perturbations including tree fall, fire, disease, drought, flood, or animal activity. As a universal cultural footprint, anthropogenic clearance is an important feature in landscape modification that contributes to changing plant and animal diversity in the forested tropics. Ecologically, indigenous gardens can be considered as mechanisms that produce higher net productivity while maintaining or increasing high diversity through a pattern of "intermediate disturbance" (Nigh and Nations 1980).

Indigenous cultivation is characterized by a wide range of land-intensive as well as land-extensive practices but is today dominated by shifting cultivation, so named because the technique usually involves leaving older gardens to fallow for periods of variable length when farmers shift their focus to preparing, planting, and harvesting newer gardens. The practice normally involves the selective clearing of vegetation in small garden plots, after which the slash can be mulched or dried and burned for additional fertilization. Indigenous gardens are diverse and multi-storied plots characterized by multiple cropping and interaction with natural vegetation. Early succession gardens often feature plantings of higher nutrient-demanding annuals requiring greater ambient sunlight. Subsequently, with increased vegetational maturity and complexity, less nutrient-demanding shade-tolerant perennials, particularly root crops, dominate later succession gardens. Over time, farmers manage and utilize

Garden Hunting, Fig. 2 Neotropical chakra or swidden garden (Jasiaquiri, Beni, Bolivia). (Photo by author)

forest fallows in an active form of agroforestry. Old fallows are returned to for various reasons and can be considered both structurally and functionally as "orchard fallows." Fallow utilization is a way to convert a system of short-term cropping into a longer-term agroforestry system; however, eventual abandonment "is not a moment in time but a process over time" (Denevan et al. 1984: 347) (Fig. 2).

Garden hunting is generally considered as an integrated feature of indigenous tropical agroecology. It is undertaken throughout the entire cycle of garden life but can continue particularly during the management of later stage swidden fallows. For the same reason that farmers who manage the succession of their fallow orchards continue to harvest relic products, these sites also continue as favorite foraging locales for eurytopic and synanthropic (wild animals living near and benefitting from humans) species. In most cases, this latter propensity should be viewed as an actively managed outcome of fallow orchards in order to take advantage of the increased productivity found in unstable forest clearings. Mosaic landscapes created by indigenous agroecological systems can be productive habitats for human populations as they provide multiple, dispersed, and productive venues in tropical forest settings. Controlled field studies in neotropical forests are identifying the ecological effects of habitat fragmentation and edge creation on the abundance and distribution of animal life. These are linked to body size, mobility, and trophic status, along with the willingness and physical ability of organisms to cross non-forested gaps, the minimum area of forest necessary to maintain normal behavior, the degree of spatial/temporal patchiness of resource distribution, and the effects of edge environments on animals (Dale et al. 1994). Fragmentation and edge creation create conditions that can favor certain synanthropic faunas which have a propensity for dramatic population increase under anthropogenic conditions. Many of these animals are preferred prey items that thrive in fragmented mosaics and thus complement the agroecological strategy of tropical agroforestry.

The production and exploitation of agroecological landscape mosaics in the past can be potentially inferred from an analysis of recovered and preserved archaeofaunal and archaeobotanical specimens. However, the reliability of these inferences is subject to many of the problems usually inherent in archaeological data interpretation, particularly those associated with assemblage accumulation and preservation. For example, the original accumulation of many of the faunas recovered at the site of deposition in an archaeological site may have actually been incidental to garden hunting. However, in certain kinds of depositional contexts, it is possible to identify the mode of accumulation in the

archaeological record based upon patterned preservation. The natural histories of incidentally accumulated faunas, moreover, might also suggest local conditions that can be used to support an interpretation that suggests habitat fragmentation. Recognizing a pattern of garden hunting in the archaeological record involves identifying a suite of eurytopic taxa that proportionately dominates the recovered sample in a cultural assemblage. These can be compared and contrasted to faunal distributions associated with continuous primary forest habitats. The relative proportions of eurytopic taxa supporting the inference of garden hunting and expressed in the form of richness and evenness values can be assessed through ubiquity measures, rank correlations, and techniques that are sensitive to sample size differences like rarefaction, regression, sampling to redundancy, and computer simulation (Stahl 2000; Stahl and Pearsall 2012).

In its first appearance, garden hunting was presented as a potential indigenous subsistence strategy practiced by pre-Hispanic neotropical horticulturalists. It was originally an archaeological interpretation that was based upon patterning of animal bone specimens recovered from archaeological contexts in forested Panama and coupled with inferences derived from ethnographic analogy and ecological observations. Critical issues surrounding garden hunting as a prehistoric subsistence strategy have been raised in archaeological studies from areas outside the tropics. Field-based studies of garden hunting by tropical subsistence farmers have also been undertaken to understand its possible implications for conservation. It has been argued that the relationship between increasing agricultural effort, human sedentism, and hunting is a complex and interrelated issue. Citing diachronic data from archaeological assemblages in the Near East, North America, and particularly the American Southwest, Speth and Scott (1989) suggest that reliance on large game actually increased in association with increasing settlement stability. This appears to have arisen independently of environmental change, demographic increase, or technological innovation. Instead, they suggest that increased reliance on large game is causally linked to fundamental socioeconomic changes associated with larger community size, residential stability, and augmented horticultural commitment. Larger and more permanent communities tend to deplete local game, while increased horticultural effort also places constraints on time and labor which involves a rescheduling of hunting effort. Additionally, the increased stability afforded by a predictable agricultural diet enables hunters to engage in greater risk-taking. Hunters, therefore, increasingly tend to spend more time farther afield pursuing larger, high-quality game. This critique, however, does not clearly define what is meant by "large" and "small" game animals nor does it substantiate how increased reliance on larger animals is established in the archaeological record. It also relies on research undertaken among neotropical, primarily Amazonian, farmers and foragers to critique the application of an hypothesis which was originally proposed for pre-Hispanic neotropical horticulturalists to archaeological assemblages in ecologically unrelated geographical areas like the desert Southwest.

Recent field-based studies of tropical horticulturalists, mainly conducted among non-indigenous small-holding ribereños and subsistence farmers, have been undertaken specifically to examine the contemporary practice of garden hunting. An 18-month study of 60 non-indigenous farms in the Peruvian Amazon found that the most common game animals above 2 kg in live weight consisted of species that regularly consume agroforestry crops. In order of importance, these included the following: agouti (*Dasyprocta*), paca (*Cuniculus*), collared peccary (*Tayassu*), tayra (*Eira*), armadillo (*Dasypus*), brocket deer (*Mazama*), and rabbit (*Sylvilagus*). Large game animals like capybara (*Hydrochoerus*), tapir (*Tapirus*), and white-lipped peccary (*Pecari*) were seldom observed (Naughton-Treves 2002). A related study of non-indigenous colonist and lowland Quechua farms in the Peruvian Amazon determined that older forests contained significantly more wildlife per unit area; however, animals were more readily available to hunters in secondary vegetation both in terms of biomass and number of collection events (Gavin 2007). It has been suggested that non-indigenous hunters prefer to pursue wild game in primary forest and

tend to spend more time there. Although anthropogenic habitats may be more productive in terms of hunting effort, primary vegetation may be preferred because of less dense understory, increased prey predictability, and the opportunity to combine hunting with the pursuit of other forest products (Parry et al. 2009). Highly prized game like paca is usually hunted in gardens and fallow, where hunting takes on the dual role of guarding crops. The choice of technology is also a factor as some hunters will not waste a relatively expensive shotgun shell on a small game item like an agouti (Naughton-Treves 2002: 498). It has been suggested that non-indigenous ribereños do not manage gardens in order to intentionally attract game, a pattern also followed by the indigenous Buglé of western Panama. Buglé hunters encounter most of their wild game within agricultural areas and do not consider it necessary to garden intentionally in order to attract crop pests that would be normally attracted anyway. The primary reason that Buglé hunt in their gardens is due to the constant threat that animal pests pose to agricultural production. As in other tropical areas of the world, garden hunting is a complementary activity that is undertaken within a broader cultural ecological pattern (Smith 2005).

International Perspectives

Garden hunting as a potential subsistence strategy has been pursued by archaeologists in different world areas, but it remains best studied and recognized in tropical areas as a complement to indigenous agroforestry. Conservation biology is particularly interested in garden hunting as it relates to conservation efforts linked to expanded farming, global deforestation, and the loss of animal biodiversity. Throughout tropical regions of South America, Africa, and Asia, secondary forests are particularly important for the acquisition of wild meat (Parry et al. 2009). Open anthropogenic landscapes are particularly productive in this regard as the tropical wildlife most likely to survive in the fragmented conditions created through farming tend to be a suit of relatively small, highly adaptable, rapidly reproducing, and pervasive faunas that include rodents, deer, and peccary in South America; cane rat, porcupine, pig duiker, baboon, and vervet monkeys in Africa; and, pig, deer, and primates in Southeast Asia (Naughton-Treves 2002). Typically, high-canopy species are rare, minimally due to canopy removal, and farmers often "clean the forest of large predators" (Naughton-Treves 2002: 499). However, the removal of large predators may also be a preventative measure, particularly by farmers who maintain domestic stock. It is particularly because of their habits that small, pervasive, r-selected, and highly adaptable eurytopic species are in low risk of extinction and consequently of no interest for conservation (Naughton-Treves 2002: 500). The higher species richness that often accompanies anthropogenic habitats also does not take into account the rare endemic species that are of particular interest for conservation (Smith 2005: 527). Conservation biology has considered secondary forests as a possible source for replenishing game depleted through hunting in primary forests (Gavin 2007). Also, hunting in anthropogenic habitats is also considered as a potential source for relieving hunting pressure of primary forest prey. Nevertheless, the former primarily consist of terrestrial species of low interest for conservation, whereas the latter include many of the canopy dwellers like birds and primates that are targeted by conservation efforts (Parry et al. 2009: 1785). Studies undertaken throughout the tropics suggest that humans do indeed prefer large wild prey over their smaller counterparts; however, the former decrease in numbers and can become locally extinct in association with settlement age (Wilkie and Lee 2004). Hunting effort is often greater in fallow forests than in primary forests and continues to be a complementary activity within agroforestry throughout the tropics. Animals are hunted and meat protein is obtained while crops are cultivated and protected from predation (Wilkie and Lee 2004: 358). Field studies have however suggested that human hunting in agroforestry landscapes does not otherwise necessarily alleviate the pressure of species loss, nor is it a strategy that is more productive than the maintenance of animal domesticates, nor does it support game biomass similar to that found in

savanna habitats. Fallow hunting currently appears to supply sufficient protein for human populations when their density is kept under four people per square kilometer (Wilkie and Lee 2004: 366). The metaphor of gardens as enclosed spaces for attracting animals, as opposed to enclosed spaces for excluding animals, has been criticized as a false allegory that was originally coupled with an ancient dream of human harmony with nature (Naughton-Treves 2002).

Gardin, Jean-Claude

Michelle Ammons
Queens College, CUNY, Flushing, NY, USA

Basic Biographical Information

Jean-Claude Gardin has not only left a lasting impression on archaeological theory but he was also an avid contributor to Middle Eastern Archaeology, as well as a pioneer for the utilization of computer and information sciences to the social sciences. Gardin, a native of France, served in the French Free Army during the Second World War, receiving the Croix du Guerre among several other honorable awards for exceptional service. After leaving the army, Gardin enrolled at the London School of Economics where he completed his B.Sc. in Economics in 1948. Gardin continued his studies at the Sorbonne in Paris where he studied Computer and Information science. His early research focused on the use of computers for organizing and cataloging the archaeological record. Later in his research, Gardin became interested in the role that cognitive sciences have in archaeology of interpretation, specifically semiotics.

Gardin's primary geographic focus was Western and Central Asia, where his publications reflect his growing interest in the semiotics of style. Gardin's use of semiotics in relation to archaeological fieldwork has influenced the recent work of several archaeologists, including that of Robert Preucel. In the United States, Gardin has been compared with Processualism, especially his research and incorporation of mathematics in archaeology. He is associated with the University of Indiana in the United States, as well as serving as director of research at the Centre National de la Recherche Scientifique (CNRS), director of studies at the Ecole des Hautes Etudes en Sciences Sociales in Paris. In 1958, he founded the Centre d'Analyse Documentaire pour l'Archéologie and in 1970 founded the Centre de Recherches Archéologiques of the CNRS. He also served as director of the UNESCO committee that produced the General Information Program (UNISIST) for the sharing of scientific knowledge and was a recipient of the Prix International de la Foundation Fyssen in cognitive studies in 1989. Gardin is also a founding member of the Arkeotek association and a member of the House of Archaeology and Ethnology at the University of Nanterre in Paris.

Major Accomplishments

The main focus of Jean-Claude Gardin's research was concentrated around semiotics in archaeological theory. He was particularly interested in how an archaeologist can look at an object and interpret its meaning. According to Gardin, one of the central issues in archaeology was the disconnection between an artifact and the interpretation given to that artifact by the archaeologist (Gardin 1997a, 2000). He strove to help create a universal system that allowed for precise classification of artifacts, ultimately leading to better communication of interpretation (Gardin 1958, 1980). In order to create this universal system for classification, Gardin introduced mathematics and scientific methodology to semiotics (Gardin 1958, 1980). The use of mathematics and scientific method in Jean-Claude Gardin's work appealed to the Processualist archaeology in the United States. Later research by Gardin involved the use of semantics in interpretation, specifically the use of declensions in descriptive analysis of artifacts (Gardin 1989a, 1997a, b). Much of his research involves the use of coding in descriptive analysis in order to achieve accurate physical descriptions of artifacts.

Jean-Claude Gardin conducted archaeological research in the Western and Central Asia, specifically in Afghanistan and the Indus Valley. His system for codes and semiotics was applied to his research on the pottery of the ancient culture of Bactria (Gardin 1985, 1998). Among the most recent of Gardin's research interests in the area include the study of artificial intelligence and the role of technology among the humanities (Gardin 1989a), as well as the role of local knowledge in archaeology (Gardin 1989b). Regarding the role

of local knowledge in archaeology, Gardin is particularly interested in the role of universal versus local semantics in providing interpretations of artifacts (Gardin 1989b: 110). Universal semantics is described as symbols that are generally accepted without argument and local semantics as more relative to a certain context and not common knowledge (Gardin 1989b: 110–111).

Jean-Claude Gardin was a pioneer for the role of mathematics and semiotics in the humanities, specifically in archaeology. His primary research included the use of semiotics in classification systems, artificial intelligence, and the importance of semantics within archaeology. His work has influenced many archaeologists regarding the use of coding to aid in descriptions of artifacts. Gardin's primary goal was to simplify classification systems and coding systems for the description and interpretation of artifacts to provide a universal system of classification to the discipline of archaeology.

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology

Eleanora A. Reber
Anthropology Department,
University of North Carolina Wilmington,
Wilmington, NC, USA

State of Knowledge and Current Debates

Gas Chromatography-Mass Spectrometry (GC-MS) is an analytical technique that allows the separation of mixtures of volatile organic compounds and the identification of each constituent compound. Due to its sensitivity, speed, versatility, inexpensiveness, and the ability to identify many different compounds in a mixture, it is a favorite instrumental technique for archaeological organic chemistry and can be applied to any substance containing volatile organic compounds. It is commonly used to analyze absorbed pottery residues, visible pottery residues, organic binders and pigments in paintings and artwork, resins, sealants, and many other substances.

Technique Background

GC-MS is the combination of two well-known analytical techniques: gas chromatography and mass spectrometry. Gas chromatography utilizes variable compound retention time on a carefully

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 1 A Thermo 1310 gas chromatograph with an ISQ single quadropole mass spectrometer (GC/MS) with attached autosampler (Credit: Dr. Chad Lane, UNC Wilmington Isotope Ratio Mass Spectrometry facility)

selected column to separate complex mixtures. The separated compounds can then be analyzed with a variety of detectors attached to the end of the GC column. In the case of GC-MS, the detector is a mass spectrometer, which allows the identification of each compound type (see Fig. 1 for a photograph of a GC/MS instrument).

When applying this type of analysis, an organic archaeological sample is dissolved in a solvent and a very small amount (1–3 μl) is injected into the GC portion of the instrument. The result is a gas chromatogram showing the presence and abundance of volatile compounds in a sample, with the area underneath each "sample peak" corresponding with the abundance of a compound (Fig. 2). If a known amount of internal standard has been added to the initial sample, the amount of each separated compound in the sample can be calculated.

Once the volatile compounds are separated by the GC, the mass spectrometer (MS) ionizes each separated compound and measures the mass-to-charge ratio (m/z) of each positive ionic fragment that enters the analyzer. The result is a mass spectrum, a graph showing the molecular weights of the ionic fragments coming from a single compound (Fig. 3). Since the molecule fragments according to the unique structure of the parent compound, each compound's mass spectrum is unique and reflects its original structure. The compound can then be identified by comparison with a sample library or with a known control sample.

One of the strengths of GC/MS analysis is its flexibility. Variations and additions may be made to the instrument and its methodology to accommodate a wide range of sample types, compound mixtures, and research questions (Fig. 4). Many variables are present in the GC portion of the instrument alone, including solvent used, injection type and temperature, carrier gas type and velocity, column type and length, stationary phase type and thickness, and temperature programming. A change in any of the variables affects compound separation, and all of these variables must be tweaked to maximize the desired result when using the GC for a large variety of archaeological science applications. Fortunately, for most archaeological science applications of the GC, there are standard instrumental methodologies to aid the investigator and give consistency to results across different laboratories (Evershed et al. 1990; Barnard et al. 2007, and others).

The mass spectrometer in most archaeological science applications is set to scan a range of ionic fragment weights, for example, from 50 to 700. This allows complete mass spectra to be produced for almost every compound in a sample. Such a scan does take a small amount of time, however,

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 2 Gas chromatograph of the total lipid extract of an archaeological pottery residue. The residue is made up of a complex mixture of lipids which have been separated by the gas chromatogram. The free fatty acids (written $C_{\text{chain length:\# of double bonds}}$) and diacylglycerols were formed during deposition by the breakdown of tri acylglycerols

and so there is a slight trade-off between sensitivity and completeness in mass spectrum detection. If a very sensitive analysis of a known compound is needed, the mass spectrometer may be run in Selected Ion Monitoring (SIM) mode, so that the mass spectrometer is detecting only a small range of selected fragment weights. This dramatically increases the sensitivity of the analysis, at the cost of not detecting any nonselected mass fragments. As a result, SIM is not appropriate for definite identifications of unknown compounds, or structural determinations of related compounds. Instruments run in SIM mode will not detect any unexpected compounds present in the sample.

In some cases, an isotope-ratio monitoring mass spectrometer is attached to the end of the GC column (GC-IRMS), with the result that the stable isotope ratios of each compound separated by the GC can be determined. The GC-IRMS is generally applied to a mixture that has already been analyzed by GC-MS, so that the identity of each compound undergoing compound-specific isotopic analysis is known.

GC-MS analysis works only on compounds that are volatile enough to vaporize in the GC column, and archaeological science applications of this technique often involve a mixture of compounds of varying (and sometimes unknown) volatility. To maximize compound volatility, a sample is often derivatized. In this procedure, a sample undergoes a chemical reaction to produce a "derivatized sample" in which most of the compounds are more volatile than the original compounds and have better GC separation than the un-derivatized parent compounds. There are many types of derivatization, but in archaeological science applications, trimethylsilyl ester derivatization (TMS esters) is often used in samples containing a mixture of compounds, including alcohols, fatty acids, terpenoids, and acyl glycerols. This type of derivatization is relatively easy, cheap, and safe to perform. Methyl ester derivatization is often used in samples consisting primarily or entirely of fatty acids. This type of derivatization adds only one additional carbon to derivatized compounds, making it especially useful in compound-specific isotope applications.

Samples of poor or uncertain volatility can also be analyzed on the GC/MS by attaching a pyrolyzer to the front of the GC column. There are several different types of pyrolyzer, but all heat a sample in a vacuum or inert atmosphere to

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 3 Mass spectrum of caffeine from *Ilex vomitoria* tea. Each line in the graph represents the molecular weight of a particular fragment from a molecule. Molecules fragment into unique patterns, which can be matched to a known reference compound

thermally decompose nonvolatile sample constituents into volatile fragment compounds. The decomposed fragments are then introduced into the GC column, and are identified using the MS, as usual. The original constituents of the sample can then be identified through the decomposed fragments in the GC (Fig. 5). Since many constituents of the mixture are fragmented prior to analysis, however, the resulting gas chromatogram tends to be more complicated than those for a GC/MS without a pyrolyzer. This technique is often referred to as py-GC/MS in the literature.

Historical Background

The GC/MS was invented in 1955 by Roland Gohlke and Fred McLafferty while working for the Dow Chemical Company (Gohlke and McLafferty 1993). The first application of gas chromatography to archaeological science was published in 1976 by Condamin et al. when they

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 4 Schematic of a GC/MS, showing the ways that various parts of it may be changed to optimize analysis for a variety of different applications to archaeological science

used the technique to confirm the survival of olive oil residues in Roman amphorae (Condamin et al. 1976). Gas chromatography alone was also used by a few analysts to analyze assorted organic materials during the 1980s (Rottlander and Schlichtherle 1979; Morgan et al. 1984, and others).

The first application of GC-MS to archaeological science was published in 1985 by Evershed et al. and identified the origin of pitch from the anaerobically preserved shipwreck the Mary Rose (Evershed et al. 1985). GC-MS was used occasionally through the late 1980s in archaeological science, generally to identify pure substances, such as sealants and adhesives (Beck et al. 1989; Heron et al. 1989a, and others).

In 1990, Evershed et al. published the first description of using high-temperature GC-MS to analyze complex mixtures of intact archaeological residues, such as pottery residues (Evershed et al. 1990). This paper began a new era of applying GC-MS in archaeological science and formed the basis for what became the standard methods of pottery residue extraction and analysis. It was soon followed by a raft of other papers utilizing the technique in a variety of situations, many produced by Richard Evershed and his students. From this beginning, GC-MS has become the standard instrumental application for the analysis of most complex organic mixtures found on an archaeological site or in anthropogenic soils, including but not limited to absorbed pottery residues, visible pottery residues, and organic binders in painting.

Compound Specific Isotope Analysis

In 1994, Evershed and colleagues first applied Gas Chromatography-Isotope Ratio Mass Spectrometry (GC-IRMS) to archaeological science (Evershed et al. 1994). In this instrumental method, the sample goes through the GC, as usual, but instead of a standard mass spectrometer, the GC column is attached to an isotope ratio mass spectrometer, which permits the analysis of the specific isotopic values for each compound in the sample. The isotopes measured depend upon the capacity of the instrument and the needs of the specific project. The most commonly analyzed isotopes in archaeological sciences are generally $\delta^{13}C$, $\delta^{18}O$, and $\delta^{15}N$, with $\delta^{13}C$ being the most

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 5 GC showing pyrolysis of primarily high density polyethylene, which normally would be insufficiently volatile to be analyzed using GC/MS. Pyrolysis has broken the nonvolatile plastic into a distinctive series of volatile compounds made up of alkenes and a corresponding alkane (Credit: Dr. Pamela Seaton, UNC Wilmington, Department of Chemistry and Biochemistry)

popular in archaeological applications of the technique, due to its usefulness in separating components from C_4 and C_3 plants in a single residue or sedimentary deposit. This technique is increasing in popularity as the instrumentation becomes more widespread, and is extremely useful in the identification of isotopically unique resources in residues and soils, such as dairy products, maize, and aquatic products (Dudd and Evershed 1998; Reber et al. 2004; Craig et al. 2011). Since the IRMS analyzes only specific isotopes, and not molecular fragments, the identity of each compound in the analyzed mixture is determined by being analyzed in parallel on a standard GC/MS, either on a separate instrument or through the splitting of the sample as it exits the GC column.

When performing compound-specific analysis of $\delta^{13}C$ values, it is important to minimize the amount of modern carbon added to a specific compound for derivatization. A correction factor must be added in order to correct for modern carbon. However, such correction always adds increased uncertainty to the result, which

increases for the number of modern carbons added in derivatization. For that reason, compounds that do not require derivatization, such as alkanes, are often preferred as a focus for GC-IRMS applications. If that is not possible, derivatization methods that add the minimum possible number of carbon atoms for each molecule are preferred.

A logical refinement of compound specific isotope analysis is compound-specific radiocarbon dating, in which the mass spectrometer measures not just stable isotope values for each compound, but also radioactive isotopes. The result is an instrumental method that permits radiocarbon dating of specific compounds in an archaeological mixture. When the correct compounds are chosen, this technique has the ability to date samples such as pottery residues or soil lipids and remove known contaminants from these complex mixtures. In order to obtain these data, however, the mass spectrometer must be extremely sensitive, and the quantities of the target compound must be adequate to obtain a good date. This technique is presently in its infancy and has largely been used in environmental reconstructions (Mollenhauer and Rethemeyer 2009). As it is further developed, however, it has the potential to be applied extensively and usefully in archaeological science.

Important Issues in the Application of GC/MS Analysis to Archaeological Science

The key issue in the application of GC-MS to archaeological science is the successful interpretation of the data from archaeological samples. Since any volatile mixture of organics can be successfully analyzed by this technique, it is easy for anyone with a background in organic chemistry to obtain results from archaeological samples. Interpretation of these results is always challenging and often problematic, however, and requires familiarity with a wide range of biochemical and chemical knowledge. Difficulties in the interpretation of GC-MS data from archaeological samples include issues in compound degradation during deposition, issues of resource mixing in organic mixtures known or suspected to come from a variety of sources, and modern contamination. Many debates surrounding GC/MS applications to archaeological sciences focus around these areas.

A good example of these issues is shown in the interpretation of pottery residues, a common application of GC-MS in archaeological science. Residue degradation occurs in two major phases. First, compounds in a residue can undergo thermal degradation during cooking and processing. Then, after the pottery sherd is deposited in the archaeological site, some of the compounds will wash into the soil, while others undergo oxidation and hydrolysis. As a result, the GC-MS analysis of an archaeological extract of a known resource often looks remarkably different from a modern extract of the same resource (Figs. 6a and b). In general, compounds with longer carbon chains survive intact for longer than those with shorter chains, while compounds with fewer double bonds (saturated compounds) survive longer than those with more double bonds (unsaturated compounds) (Eglinton and Logan 1991). This problem varies according to environment, with dry and anaerobic environments providing the best preservation for organic compounds. The probable loss and degradation of compounds in an archaeological mixture must always be kept in mind during interpretation.

Many resources contain a similar suite of common fatty acids linked to glycerol backbones, producing acyl lipids. To identify a specific resource through GC/MS, biomarkers are required. Biomarkers are compounds that are unique to a particular resource or class of resources. For example, the presence of cholesterol in a pottery residue allows a confident interpretation of animal or fish products being processed in a vessel. Plant sterols, such as sitosterol, campesterol, and stigmasterol, indicate the presence of plant processing. Much of modern GC-MS analysis of archaeological resins, sealants, residues, and soils rests on the identification and detection of such biomarkers. Plant resins, chocolate, marine resources, tobacco, and other resources all produce biomarkers known to survive in the archaeological record (Mills and White 1977; Hurst et al. 1989; Hansel et al. 2004; Evershed 2008, and others). An important part of biomarker interpretation is a solid knowledge

Gas Chromatography-Mass Spectrometry (GC-MS): Applications in Archaeology, Fig. 6 (**a**) GC showing the total lipid extract of a Black Drink tea extracted from a pot immediately after the pot was used to produce the tea. Unlabeled compounds are largely sugars and glucopyranosides. Sitosterol is present in this residue, but is masked by other compounds and is not visible in the GC (**b**) GC showing the total lipid extract of the same Black Drink pot from a after it was buried for 1 month in a sandy loam acidic soil. Note the loss of many sugars and pyranosides, although some are still present. Caffeine is now much more visible in the residue, as are free fatty acids and sitosterol. This is partially due to the loss of the abundant sugars and pyranosides from 6a, but also due to diagenesis of more complex compounds, such as chlorogenic acid-caffeine complex and acyl lipids. These reactions become more complete after 1 month, and the archaeological residue continues to change

of the biome from which an organic sample derived. Many biomarkers may exist in several different resources around the planet, but be unique in a particular biome. For example, caffeine detected in a residue from Mesoamerica generally indicates chocolate, while the same compound identified in a Chinese residue would indicate tea, and in the Southeastern United States would probably indicate *Ilex vomitoria*, the main ingredient in Black Drink. If trade is suspected, secondary biomarkers and/or archaeological evidence must be used to distinguish the resources (Washburn et al. 2014).

Compound-specific isotope analysis using GC-IRMS may be used in some circumstances to help in the analysis of mixed residues, such as when an isotopically unique resource or resources is present in the mixture in large enough amounts to affect the stable isotope ratios of a given compound. As in any isotopic study, a good understanding of the archaeological biome is crucial when performing compound-specific analysis. For example, a compound-specific carbon isotope analysis of fatty acids may detect a primarily C_4 component in fatty acids or other compounds from a residue. If the residue is from eastern North America, the source of the C_4 component is probably maize (Reber et al. 2004). If the residue originates from another biome, the source of the C_4 component might be completely different. Further discussion of the application of GC/MS analysis to pottery residues is included below.

Modern contamination is also an issue in the interpretation of GC-MS analysis of archaeological samples. Due to the sensitivity of the technique and its ability to separate complex mixtures, a wide range of contaminants has been identified in archaeological samples. Modern fertilizers and pollution in the soil may contribute contaminants to a sample before excavation. During excavation, compounds from excavators' bug spray and sunscreen often contaminate an artifact and are detected in the GC/MS analysis. Since many sunscreens and bug sprays include acyl lipids, this form of contamination affects the interpretation of fatty acids in the sample. After excavation, contamination from modern plasticizers is ubiquitous and appears to be exceptionally difficult to eliminate, while archaeological labeling procedures are also a common source of contaminants. Samples stored in museum shelves in open storage are vulnerable to contamination from modern caffeine and possibly other substances (Washburn et al. 2014). For this reason, all samples taken for GC-MS analysis should ideally be handled minimally by excavators and placed in lipid-free aluminum foil in the field. Contact with plastic bags should be minimized if possible. That said, the ability of GC-MS to separate complex mixtures means that contaminants, if correctly identified, may be separated from the remainder of the sample with minimal problems to interpretation.

When to Use GC/MS

A secondary issue in GC-MS analysis is the correct selection of instrumental analysis. GC-MS is generally the best instrumental technique to use when a complex mixture of volatile organic compounds is known to be present. When a complex mixture of nonvolatile compounds is present, Liquid Chromatography-Mass Spectrometry (LC-MS) is preferred. High Pressure Liquid Chromatography/Mass Spectrometry (HPLC-MS) has recently been successful in detecting trace amounts of less volatile biomarkers in pottery residues, such as caffeine and capsaicin (Hall et al. 1990; Powis et al. 2013, and others). If a substance is known to come from a single source, then Fourier-Transform Infrared Spectroscopy (FTIR) analysis may be considered, although it does not allow for the separation of different compounds in a mixture. If a mixture contains a mixture of volatile and nonvolatile organic compounds, derivatization or py-GC/MS may allow the analysis of the entire mixture by GC-MS.

Application of GC/MS to Resins and Sealants

The analysis of resins and sealants was the earliest application of GC/MS to archaeological science (Evershed et al. 1985). GC/MS is especially well suited to resin and sealant analysis for several reasons. Many archaeological and historical incenses, sealants, and glues are organic in nature, deriving from plant sap or resin or bitumen,

meaning that these compounds are volatile when derivatized. They separate and identify very clearly on GC/MS. Further, many resins are relatively simple mixtures, deriving from a single natural source, which may have been additionally heated or processed. When the analyst is faced with such a resin, it is reasonably certain that GC/MS can analyze the entire sample. Constituent compounds in many resins and sealants are chemically stable and contain a variety of well-known biomarkers, both for the source of the resin and for heating or processing (Mills and White 1977; Stern et al. 2003, and others). As a result, GC/MS analysis of resins and sealants tends to give a clear indicator of the source of the resin or sealant and its processing.

Many resins or sealants derive from some sort of coniferous resin (Mills and White 1977; Colombini et al. 2003, and others). Coniferous resins are generally distinguished by their diterpenoid constituents, which vary, sometimes dramatically, between different families of conifers. Resins deriving from members of Pinaceae, for example, contain abundant abietane and/or pimarane diterpenoids, and their identification is fairly routine. Furthermore, these diterpenoids oxidize to stable compounds – abietane diterpenoids regularly oxidize to dehydroabietic or 7-oxodehydroabietic acid during deposition (Mills and White 1977) or retene in the presence of regular heating such as the production of pitch or turpentine from pine (Mills and White 1977; Evershed et al. 1985). For these reasons, the biomarker compounds are especially stable, and processed pine resin may be distinguished from unprocessed resin. Resins from Cupressaceae contain more pimarane diterpenoids and communic acid, a type of labdane diterpenoid, while those from Araucariaceae contain an unusual mixture of abietane, pimarane, labdane, and kaurane diterpenoids (Mills and White 1977). These compounds are also generally stable in the archaeological record.

Resins and sealants may also be derived from non-coniferous plants, as in frankincense, Protium copal, Bursera resin, resin from leguminous members of Fabaceae, resin from various species of *Agathis,* birch tar, and gum mastic (from members of genus *Pistacia*), among many others (Mills and White 1977; Langenheim 2003, and others). Leguminous resins appear to be comprised primarily of labdane diterpenoids, which therefore occur in both coniferous and non-coniferous resins (Mills and White 1977). In most other cases, nonconiferous plant resins are distinguished by a variety of triterpenoid compounds, some of which are biomarkers for a specific genus or family of plant (Mills and White 1977; Stern et al. 2003, and others). These compounds are also stable and can be separated and identified using GC/MS (Mills and White 1977; Heron et al. 1989a).

Bitumen, tar, or asphalt have also been used as sealants in the past in a variety of locations (Connan et al. 1992; Serpico and White 2000). These hydrocarbon-derived sealants may be identified by the standard biomarkers for crude oil, especially hopanoid terpanes, polyaromatic hydrocarbons, and a complex mixture of aromatic compounds including asphaltenes (Serpico and White 2000, and others).

Application of Gas Chromatography/Mass Spectrometry to Pottery Residues

GC/MS is commonly used to analyze organic pottery residues, either absorbed within the wall of a pot (an absorbed residue) or encased in carbon on the interior surface of a pot wall (a visible residue). Absorbed residues are often comprised primarily of a complex mixture of lipids, as discussed above. Visible residues often contain lipids in addition to other types of elements such as starch and proteins, (Heron et al. 1989b; Thompson and Staller 2000, and others). In both types of residue, however, the residues are comprised of a complex mixture of compounds, many of which are volatile. As a result, GC/MS is the preferred instrument type for most pottery residue analyses, unless the project is specifically focused on a resource with a biomarker that is better suited to HPLC/MS or another type of instrumental analysis. Pottery residues are archaeologically important because their analysis allows a direct understanding of pottery use in a culture. This often allows a much clearer understanding of the ways that ancient people processed food and other

substances, casting a light on cultural practices that would not otherwise be detectable by the archaeologist.

Interpretation of GC/MS analysis of pottery residues is complex, because pottery residues often derive from a variety of sources. An extracted organic pottery residue is comprised of a mixture of lipids, including acyl lipids, fatty acids, long-chain alcohols, alkanes, terpenoids, and many other compound types. Unless the pottery vessel was known to have processed only one resource, these compounds cannot be assumed to have come from the same source. Often, these compounds were derived from all the resources processed in a vessel over its lifetime. For example, the common fatty acid $C_{16:0}$ (palmitic acid) in a residue may derive from literally every resource ever processed in a pot, with no way of knowing how much of the compound derived from any one resource. For this reason, interpretations of vessel contents based only on common compounds such as fatty acids and acyl lipids tend to be problematic, aside from issues of oxidative and bacterial degradation mentioned above (Reber and Evershed 2004). Although single source resources often have distinctive fatty acid ratios (Malainey et al. 1999), in the case of mixed-use vessels a general interpretation of "primarily vegetable in origin" (more unsaturated fatty acids, and more abundant $C_{16:0}$ vs. $C_{18:0}$ fatty acids) or "primarily animal or meat in origin" (more saturated fatty acids, and more abundant $C_{18:0}$ vs. $C_{16:0}$ fatty acids) is usually the most precise interpretation that can be derived from fatty acid and acyl lipid abundances. This is generally disappointing to the excavator, who was hoping for a more precise characterization. An exception to this issue is present in the case of vessels that are known to have contained only one resource, such as transport amphorae and labeled chocolate pots.

Because of resource mixing in many pottery vessels, biomarkers are required for a more precise description of vessels contents. As described above, sterols are probably the most commonly used biomarkers in absorbed residues, with cholesterol and plant sterols allowing the presence of animal-based and plant-based foods to be definitively identified. Depending upon the contents of the vessel, a variety of other resources may be identified in pottery residues using biomarkers, including resins and sealants as described above, aquatic resources, nicotine, caffeine-containing resources (which vary by biome, as described above), a variety of psychoactive plants, and waxes (Evershed 2008). Probably unique to pottery residues are pyrolytically formed biomarkers – unique compounds that result from the heating of chemically unstable compounds within the pot walls. Polyunsaturated fatty acids, normally chemically unstable during deposition, undergo pyrolysis to ω-(o-alkylphenyl) alkanoic acids, which are stable in the archaeological record (Hansel et al. 2004). These compounds allow the detection of fish or marine resources that contained unstable polyunsaturated fatty acids otherwise unlikely to preserve in the archaeological record. A similar process occurs in the formation of ketones from fatty acids at temperatures above 300 ° C (Evershed et al. 1995).

In the absence of biomarkers, compound-specific isotopic analysis allows an analytical pathway to address resource mixing, if resources are present in the residue that can be distinguished isotopically. When used to identify dairy, aquatic resources, porcine fat, or another lipid-rich resource, isotopic mixing in fatty acids may relatively easily be detected (Dudd and Evershed 1998; Craig et al. 2013, and others). Among other things, this application of GC-IRMS has allowed a better understanding of the importance of dairy products and aquatic resources in archaeological foodways (Craig et al. 2013; Evershed 2008).

Identifying cereal grains in a pottery residue is complicated by the fact that these grains are often primarily comprised of starch and are lipid-poor. As a result, common lipids from fattier resources may overwhelm the signature from isotopically unique grains. In these cases, compound-specific isotope analysis is most effective if focused on compounds that are more abundant in plant than in meat resources, such as alkanols or alkanes (Reber et al. 2004). Maize is most effectively detected in absorbed residues by compound-specific isotopic analysis of the long-chain alkanol *n*-dotriacontanol, for example, although

it may also be identified using other compounds (Reber et al. 2004).

The literature on GC/MS application to pottery residues is voluminous and has produced a fairly standardized methodology in terms of extraction, derivatization, instrumental method, and interpretation, albeit one that is constantly being refined and improved (Barnard et al. 2007, and others). Lipid residues have been successfully extracted and interpreted from Incipient Jomon pottery (Craig et al. 2013) and from pottery existing at the foraging/farming transition in Europe and North America (Craig et al. 2011; Tache and Craig 2015). These applications demonstrate the potential of GC/MS analysis of pottery residues to address issues of archaeological importance across a longer-than expected time range.

Extraction of absorbed residues from pottery is destructive, requiring sample sizes of at least 1 g of sherd (and usually more), and relatively labor-intensive in the laboratory. Recent innovations in GC/MS applications to pottery residues have tended to focus on this process. Direct acidic or alkaline extraction of residues from potsherds appears to both increase the amount of lipid extracted from pottery and speed the extraction of lipids from powdered sherds. This allows larger numbers of samples to be analyzed in the same time period and with smaller sample sizes (Craig et al. 2013; Correa-Ascencio and Evershed 2014). To minimize destruction in the case of museum-quality or vessels of archaeological importance, powdered sherd is sometimes removed from the interior of a vessel through abrasion, rather than powdering an entire sherd (Washburn et al. 2014).

Application of GC/MS to Pigments and Binders

The application of GC/MS to pigments is relatively difficult, because of the nonvolatile nature of many pigments, especially those derived from mineral sources. Py-GC/MS has been used to identify organic pigments, as well as cinnabar and other mercury-based pigments (Wei et al. 2012; Gebremariam et al. 2016).

Binders used in archaeological and historical painting are often derived from organic sources, however, and GC/MS is generally considered the preferred instrumentation for their analysis. Owing to the difficulty of separating pigments and binders in many applications, GC/MS or py-GC/MS is often used in combination with another method or methods more applicable to the identification of nonvolatile compounds and pigments, such as FTIR, Energy Dispersion X-ray microanalysis, Raman spectroscopy, X-ray fluorescence (XRF), or X-ray diffraction (XRD) (Colombini et al. 2003; Duran et al. 2010; Gebremariam et al. 2016). This allows the identification of inorganic pigments, organic pigments, and a variety of binders, giving a complete reconstruction of the painting method used.

Commonly used binders include plant resin (pine sap, gum mastic, gum Arabic, etc.), beeswax, animal glue, milk, garlic, and egg (Colombini et al. 1999; Duran et al. 2010, and many others). Plant resins may be identified using many of the same methods and biomarkers as the plant-based sealants described above, and are often the same or similar plant resins to those used as sealants or glue. Beeswax is distinguishable by its unique pattern of wax esters, alkanes, and alkanols (Colombini et al. 2003; Regert et al. 2003).

Animal glue is generally made up of a collagen-based polymer produced by boiling animal products such as skin, bones, or hooves; it is very proteinaceous and is high in the amino acids glycine, proline, and hydroxyproline; hydroxyproline is often used as a biomarker for animal glue (Wei et al. 2012, and others). Egg, milk, and garlic binders are similarly proteinaceous. The amino acid constituents of these proteinaceous binders may be identified through py-GC/MS (Gebremariam et al. 2016; Wei et al. 2012) or on GC/MS after derivatization (Colombini et al. 1999). Proteinaceous binders such as eggs, milk, animal glue, and garlic may be distinguished by relative abundances of various amino acids (Schilling and Khanjian 1996; Gimeno-Adelantado et al. 2002, and others). Often, statistical analyses such as Principal Component Analysis (PCA) are used to compare amino acids detected in binders with aged standards produced in the laboratory (Colombini et al. 1999; Gimeno-Adelantado et al. 2002, and others). This method

is useful in most cases, but it is important to remember that both the historical literature and archaeological science suggest that ancient artists occasionally mixed substances together to produce a complex binder, which would be intermediate in values to the controls (Gimeno-Adelantado et al. 2002; Duran et al. 2010).

Compound binders from nonproteinaceous sources, or from a mixture of proteinaceous and resin-derived sources, would produce mixtures that would contain multiple biomarkers, and/or resin biomarkers with the addition of typical amino acids for proteinaceous binders. Further, in the case of frescoes, damp lime plaster or lime water was used as a binder, which is nonorganic. A nonorganic binder could not be identified using GC/MS or could be identified only through the absence of the indicators for organic binders.

Applications of GC/MS and GC-IRMS to Soils

Soil chemistry is largely comprised of a very complex mixture of lipids, lignins, and decayed leaf litter that may also be analyzed through GC/MS, py-GC/MS, and GC-IRMS for a variety of applications. Analysis of these chemicals in closed context is often most effective, as soil chemicals often leach into and out of soil layers in open contexts.

Manure and Fecal Biomarkers

Digestion of foodstuffs in the guts of most animals produces a distinctive set of biomarkers, 5-β-stanols and bile acids (Bethell et al. 1994; Evershed et al. 1997), which are known to persist in soils over long periods of time. The precise type of 5β-stanols produced through digestion depends on the original foodstuff – coprostanol is produced by the breakdown of cholesterol (Bethell et al. 1994), while 5β-stigmastanol is produced by the breakdown of vegetation (Evershed et al. 1997). In this way, fecal biomarkers from human or other omnivorous animals (for example, pigs and dogs) may be distinguished from biomarkers deriving primarily from herbivores, such as cows or horses. Other types of stanols indicate a variety of breakdown processes that take place in sterols and stanols. For example, epi-5β-stanols may form from 5β stanols through microbial breakdown, and this compound type is often used as an indicator of deliberate composting of dung (Bull et al. 2001).

Given the complexity of soil and microbial interactions present in areas with an abundant presence of feces or manure, a series of ratios of different sterol/stanol types has been proposed to distinguish a variety of specific applications of this technique – fecal or manure presence vs. natural soil stanols, feces from primarily omnivorous animals vs. herbivores, and fresh manure vs. compost (Evershed et al. 1997; Bull et al. 2001, and others). This specific application of GC/MS to soil chemistry is generally used in areas where the excavator suspects the presence of a latrine or heavy manuring for archaeological reasons. It has been used to confirm the presence and use of latrines in a variety of places (Shillito et al. 2011) and to determine manuring in fields (Bull et al. 2001, and others).

Environmental Reconstruction

Although soil lipids do migrate in a variety of ways depending upon the individual geomorphology and environment for an area, GC/MS may be applied to soil columns to produce a broad environmental reconstruction of a site or regional area. Py-GC/MS is often used in this application, as it can be used to break down cellulose, lignin, suberin, and other nonvolatile soil components deriving from plant polymers. This allows a reconstruction of type and amount of organic matter present in a soil layer (Almendros et al. 1998). Presence of abundant burning is indicated by biomarkers such as polyaromatic hydrocarbons (PAHs) (Kaal et al. 2008), which are present either during burning or in crude oil (Ocean Sciences Board 1985). In the absence of a known source of hydrocarbon oil contamination, therefore, PAHs may be used to indicate abundant or increasing fire episodes. This can be used as a proxy for human land clearing through fire or climate change leading to increased fire incidence (Tallón-Armada et al. 2014). In these ways, broad environmental changes around a site may be distinguished through application of GC/MS to soil columns. These applications are often best

used in tandem with a variety of other analysis types that can be used to confirm the changes in soil chemistry, notably charcoal and pollen analyses. In performing this type of analysis, it is crucial to remember the potential of soil lipids to migrate in a variety of ways.

More anthropocentric changes to the environment can also be detected using compound-specific isotope analyses of compounds in soil columns and lake-bed sediment cores. In an environment where the biome is predominantly C_3 (or C_4), the advent of abundant C_4 (or C_3) agriculture may be detected by compound-specific analyses of leaf wax components washed into lake beds or preserved in soil columns. As the native C_3 plant cover is removed and replaced by C_4 crop fields, the organic matter in fields and washed into lake-beds becomes measurably more enriched in $\delta^{13}C$ (Webb et al. 2007; Lane et al. 2008). Alkanes are often preferred for this type of analysis, as they do not require derivatization. The advent of intensive maize agriculture in Mesoamerica, Costa Rica and parts of the Caribbean (Lane et al. 2009, and others) as well as the decrease in maize agriculture in the Mayan Lowlands following the Terminal Classic period have been determined using this technique (Webb et al. 2007, and others).

Application of GC/MS to Amino Acids and Proteins

GC/MS is not normally the preferred choice for protein and amino acid analysis. Proteins are nonvolatile and are better suited for HPLC/MS analysis than GC/MS analysis (Barker et al. 2012).

In order to analyze proteins using a GC/MS, the analyst must assume that the protein is already breaking down into constituent amino acids due to natural diagenetic factors, or must initiate this breakdown as part of a laboratory or instrumental method (Schilling and Khanjian 1996). Py-GC/MS is often used to pyrolyze proteins into amino acids, which may then undergo separation and identification. For GC/MS analysis without pyrolysis, the amino acids must undergo some form of derivatization, as discussed above. Because of this analytical complexity, GC/MS analysis of proteins and amino acids are most useful when investigating complex mixtures of lipids and proteins, such as paint binders (discussed above), lacquerware, or visible pottery residues (Oudemans and Boon 1991; Wei et al. 2011, and others).

Future Directions

The power and flexibility of GC/MS analysis makes it almost indispensable for the analysis of any type of complex organic mixture believed to contain at least some volatile compounds. The increased availability of GC-IRMS instruments will allow compound-specific isotope analysis to be applied over a wider range of resources going forward, which will further allow more precise and culturally informative interpretations of archaeological resource use.

As more background research is performed, more biomarkers will be identified. As a result, the number of biomarker identifications of prehistoric resources in a residue will increase. That said biomarker identification is becoming an increasingly complex process. Because of diagenesis, oxidation, microbial breakdown, and hydrolysis of archaeological organic compounds during burial, biomarkers are often best detected by examining archaeological resources, rather than modern control samples. Many compounds proposed as biomarkers from modern resources undergo unexpected transformations during burial, and do not survive in the archaeological record in their original form. As many of the most distinctive organic substances have already been identified, future biomarker identification will probably become increasingly complex and dependent upon large numbers of archaeological samples undergoing analysis.

In terms of archaeological interpretation, the next step in GC/MS applications to archaeological science will also lie in increasingly large numbers of samples undergoing GC/MS analysis to answer-specific archaeological questions. Such sample sizes can be used to answer questions regarding trade, specific resource use, changes in

pot use over time, and varying uses of varying vessel types at a site. These questions are of archaeological importance and cannot readily be answered without a carefully chosen group of at least 100–200 samples (Evershed 2008; Craig et al. 2011; Tache and Craig 2015).

Increasing interaction and understanding between archaeologists and GC/MS analysts will be essential in future applications of the technique. Ideally, the GC/MS analyst should understand the archaeological issues at question. Misunderstandings between the excavator and analyst can result in a flawed project and considerable frustration (Mazow et al. 2014).

In general, therefore, the future direction of GC/MS applications to archaeological science will involve increasing application of the technique to a variety of specific archaeological questions. With increasing communication, and a better understanding of the technique, GC/MS analysis should enter the standard repertoire of archaeological techniques around the world.

Gavà Mining Site: Fieldwork

Josep Bosch
Gavà Museum, Barcelona, Spain

Brief Definition of the Topic

Gavà, a village by the sea at the mouth of the Llobregat river in the northeast Iberian Peninsula, is the site of the only known Neolithic mine in Europe extracting *variscite*. This green mineral, similar to turquoise, is found in Neolithic tombs; its color is probably linked symbolically with the regeneration of life. At Gavà it occurs as seams of slate within layers of limestone and dolomite or sealed under clay where it outcrops. The prehistoric miners followed the seams, digging shafts leading to tunnels between 5 and 10 m long and about 2.5 m wide. These later expanded into more complex galleries with chambers, reaching depths of 30 m and more. In general the prehistoric mining cavities had been backfilled with extraction debris, including broken mining tools (stone picks and bone wedges); this saved the labor of transporting it outside the mine. Some of the cavities were reused as graves in Neolithic times (Figs. 1 and 2).

The first task of archaeological investigation was to make the mining galleries safe. Shoring with metal frames and concrete, as in modern mining, was unsuitable, as it would mask the surface of the rock, where prehistoric tool marks are still visible. Instead, metal anchors are placed on the rock with a resin coating that protects and secures the surface. Cracks and fissures are also filled with resin. The rock surface is impregnated with a product that allows moisture to escape. Humidity and the flow of water inside the mines are controlled with high precision, and warning instruments monitor the stability of the rock.

Excavation to date has focused on the deposits inside the mine. A full stratigraphic record of the strata in the galleries, chambers, and minor cavities is being made, both to define any features such as the graves and to investigate the patterns of extraction and discard noted in the debris. The assemblage includes different kinds of lithics, ceramics, and animal bones. Systematic screening maximizes recovery and has allowed the find of a variscite necklace. The date of the mining, from radiocarbon, is between 4100 and 3400 cal. BCE.

Gavà Mining Site: Fieldwork,
Fig. 2 Restoration of one of the mines (Museu de Gavà, Benet Solina)

After nearly four decades since its discovery, a sizable, but unknown, proportion of the mine has been examined. The mine was declared a site of National Cultural Interest in 1996, and there is a plan to open it to the public once safe access and robust conservation measures are in place.

Gender and Feminism in Brazilian Archaeology

Camila Jácome[1] and Laura Furquim[2]
[1]Anthropology and Archaeology Program, Federal University of Western Pará, Santarem, Pará, Brazil
[2]Museum of Archaeology and Ethnology, Department of Archaeology, University of São Paulo, São Paulo, Brazil

Forewords

From the history of formation of Brazilian archaeology and its great themes, we will discuss in which manner *gender* issue has been worked in research and practice, as we will treat the presence (and in many cases, the absence) of women in archaeological past. In Brazil, colonialism, racism, and sexism are the foundation and structure of society and dominant classes, which includes intellectuals and knowledge sources. Historically, European and North American concepts were imported to the interpretations regarding native and traditional populations (*quilombola*, riverine, among others). (*Quilombolas* are traditional groups that may or may not has historical

connections with the *quilombos*, communities created by Afro-Americans that escaped slavery in the colonial period, is today an important social and cultural identity of struggle and resistance to racism and social inequality that structure the Brazilian society.). This has resulted in the erasure of emic perspectives regarding gender, identity, and personhood. The classifications and periods developed to explain the history of Americas are based on foreign civilizational parameter that made inviable the ethnicity of indigenous and African people, be it in the archaeology made about periods before or after the European invasion. Typological concepts, such as "hunter-gatherers," "Neolithic," "ceramists," "Formative," among others, are being discussed again and substituted for not representing the *modus operandi* of American native societies.

A similar process has occurred in relation to gender discussions in the discipline. Brazilian archaeology has been constructed as an empirical scientific endeavor, the ultimate goal being the production of objective and verifiable facts, under the paradigm of neutrality, of unequivocal facts, and of scientific objectivity. In part, this supposedly neutral model of archaeology is necessitated by the need for primary investigations into archaeologically unknown contexts throughout the country where no previous research exists. Because of this model of archaeology, allied to the necessity of making new researches in unknown contexts and to a scientificism focused of the production of numeric data (sites, excavation, quantity and statistics of archaeological material, dating, etc.), Brazilian archaeology has long denied itself to incorporate gender theory and feminist and *queer* critics in its research agenda.

There is a fusion between narrative parameters from historic-culturalism and processual methodologies that difficult the visualization of a delimited distinction between classical archaeological schools, as is proposed by Trigger (1989) to European and North American context. In such places, the breakage of Eurocentric paradigm promoted by postprocessual (or postmodern) archaeology has brought to its agenda the political feminist movement and the critics of a parameter of heterosexual and white masculinity as a "neutral gender" of pre- and postcolonial past. The first Brazilian researches that evoked gender issue brought an evolutionary baggage based on sexual dimorphism and in the binary correlation between sex (masculine and feminine) and gender (man and woman). Only in the last decade, some stank conception about the roles played by different social segments have been coming out. As says Ribeiro (2017), it is still necessary to undergo a process of unlearning the modern conception of gender and of questioning diverse practices of relationship involving ethnicity/race, age, sexuality, activities, among others.

The "origins," a noble issue in Brazilian archaeology, specifically the origins of sexual division of labor, has been incorporated in interpretations about the past, considering the origins of gender inequality and the paradigm of universal masculine domination (seen, always, through a binary lens): hunters – men/ceramist gatherers – women, and so on. Thus, indigenous gender categories were invisibilized and diluted in the sexual dimorphism. Ethnography, for a long time, has demonstrated that indigenous genders and bodies are much more complex constructs, such as the classical work of Pierre Clastres (1972) among the Aché Gatu, in which he demonstrates that gender is not related only to labor division but also to the abilities that people can acquire or lose. If a man, for example, loses his abilities (or luck) in hunting he becomes *panema*. (*Panema* is a word present in several tupi-guarani languages, which means unlucky, unhappy, bad, unproductive, sterile (Tupi-Guarani – Portuguese Vocabulary, Silveira Bueno 2008).) If he does not assume the condition of *panema* and go to gather activities with women, he will become a displaced individual in the group.

This entry is organized into four parts. The first is dedicated to introduce the pioneering researches in precolonial archaeology from the 1980s and 1990s and some more recent ones that bring gender issues. Those works brought gender issue to Brazilian archaeology, especially through

bioarchaeology and archaeology of symbolism (e.g., rock art, Amazonian ceramic, among other). In the second, we are going to focus on researches about historic archaeology and the evidences about the roles played by women represented in material culture, architecture, and historic documentation. Then, we will bring some perspectives on gender discussed by anthropology regarding indigenous identities that can be used as guides to new perspectives on this theme in Brazil. Finally, we will present a very recent scenario, in which archaeologists have debated not only about gender and *queer* theories, but also with a theoretic and political feminism. This last entry is dedicated to relationships of labor (the present ones) and researches in the professional and academic environments.

We cannot deny the pioneering of women in the development of archaeology since the beginning of the twentieth century, both Brazilian and foreign, which are responsible for part of the scientification in the Brazilian field. However, beyond those "founder" women (Sombrio 2006), there is a mass of unknown women producing knowledge in the country. As pointed by Ribeiro et al. (2017), besides the majority of the intellectual production in last years having been done by women, only a small part of them reach research coordinator positions. Their production is rarely mentioned by their colleagues and only a few are included as reference in under-graduation programs. If we turn to Amazonian archaeology, where the protagonist of Betty Meggers (1971) and Anna Roosevelt (1991) influences the researches until today, we will see something very similar. Although most part of the research is developed by women, mainly young and writing most of the articles, they are less quoted than men, and their production has smaller impact away from this geographic and academic area (Caromano et al. 2017). For all those questions, we will champion female writers in this entry, not only because archaeology has a historical debt to them but also to make justice to reality of this theme in Brazilian research, which is conducted mainly by women.

Gender in Precolonial Brazilian Archaeology

In the 1980s, some Brazilian archaeologists began to highlight the role of gender in their research. This focus coincided with the increasing prominence of feminist scholarship in Brazilian academia during the decade, as part of an institutional agenda of Brazilian archaeology, mainly those conducted by women. In those initial moments, these archaeologists used a binary interpretation of gender to identify the sex in the archaeological record, primarily through skeletal data and symbolic representations of human bodies in artefacts and rock art paintings. This research built on Margaret Mead's (1969) anthropological work on the social construction of feminine and masculine roles in indigenous North American societies. Through this frame, archaeologists sought to identify evidence of gendered activities in the past as a means to evaluate the existence gendered inequalities and hierarchies. This same research paradigm can be identified in studies on shellmound societies of southern Brazil (States of Rio de Janeiro, São Paulo, Santa Catarina, Paraná, and Rio Grande do Sul) (Gaspar et al. 2011; Escórcio and Gaspar 2005; Escórcio 2008), indigenous peoples of the Xingó region (Bahia state) (Lima 2012), and Capivara Hills (State of Piauí) (Pessis 2005; Castro 2010) and in rockshelters from Minas Gerais state (Sene 2007) (See Fig. 1 for the location of archaeological areas).

Many of the first known archaeological sites in the south, southeast, and northeast of Brazil, such as rock shelters and shellmounds dated from the Initial and Middle Holocene (c. 12.000–3.000 A.P.), are cemeteries with large numbers of buried individuals. Archaeologists working in these contexts have primarily investigated sexual divisions of labor and status at time of death by examining sexually dimorphic skeletal markers, pathological indicators, and ceremonial grave goods. For instance, Gaspar and Escórcio (2005) synthesized the several elements of material culture present in feminine and masculine burials in shellmounds of the coast (Fig. 2) and concluded that distinct labor activities between men and women would have

Gender and Feminism in Brazilian Archaeology, Fig. 1 Map of the mentioned archaeological regions. Cities: 1. Pelotas (Rio Grande do Sul). 2. São Sebastião (São Paulo). 3. Gender and Feminism in Brazilian Archaeology, Fig. 2 Cabeçuda Shellmound (Santa Catarina state). A young woman (18–20 years) buried in a shallow pit in a ventral decubitus dated from 2900 B.C. (GRUPEP/UNISUL's collection photo)

been based around nonhierarchical system of cooperation. Notably, this goes against long-held traditions in Western thought that view patriarchal domination as a universal aspect of human sociality. Artifacts that should be, according with stereotypes that were crystalized in *Man the Hunter* (Lee and Devore 1968), connected to activities of hunting (bone and lithic tips and axes) and to the hunter status (necklace made of animal teeth) were equally present in feminine and masculine burials. Those artifacts should represent the roles of the buried person.

Based on material culture and burials dated to the Middle and Late Holocene in northwest Brazil, Lima (2012) has concluded that it is not gender relationships that structure the culture of the groups she studied, but the hierarchic relationships of social sectors within those communities, according to kinship relations. Even so, paleopathologic markers in human teeth (i.e., enamel hypoplasia) indicate that, even though men and women were able to participate in the same activities of food preparation of foodstuffs and artifacts, they nonetheless had differential access to food consumption during childhood.

Such research carries the embryo of complexification of gender issues through an anthropological perspective – that is going to be developed further – with the linkage between biological characteristics of sex, age, identity, individual status, among other questions. Even so, "genders are studied based on an individual's sex" and in the distribution of activities and related artefacts (Lima 2012: 21), showing a correlation between biological sex and gender identity in the interpretation of data. The differences of diets among children with feminine and masculine bodies (always in a binary sense) are attributed to "feeding privileges" and indicate that we still have much to learn about the construction of identity during childhood in these societies, specially regarded to feeding restrictions in periods of *tabu* and seclusions (Morim de Lima 2015).

This kind of identification also came out of studies of symbolic forms of human representation, especially in rock art traditions of northwestern Brazil. There are two principal types of archaeological sites in the Capivara Hills, State of Piauí, that allude to sexual scenes utilized in studies regarding gender distinctions (Fig. 3). Paintings from the Várzea Grande tradition have several dynamic representations of human figures engaged in hunting, dancing, and other activities. Copulation scenes which clearly express sexual differences through exaggerated representations of the penis and vagina are very common. We highlight the pioneering of Gabriela Martins and Anne Marie Pessis (Pessis and Martin 2005) on this issue in Brazilian archaeology. After them, there is a tradition of research on sex and gender in rock art, which combines perspectives of gender identification based on the presence of sexual organs to what is supposed to be the sexuality patterns of the past.

Gender and Feminism in Brazilian Archaeology, Fig. 3 Rockshelter Toca do Vento (Piauí state). Above three anthropomorphs with erect penis and erect arms, to the left center a combat scene, in which an anthropomorph hits another with instrument, below the sex scene, apparently heterosexual, and below and left, sex scene with a pregnant woman. (Photo: Andrei Isnardis)

Those works also care about the issue of sexual division of labor and are, in a way, used as source of information about prefarmer indigenous societies. As argued by Pessis (2005), the origins of agriculture would have been accomplished by a hierarchical division between men and women based on unequal access to technical knowledge and on male control over that knowledge. In contrast to this model, the early rock art depictions at Capivara Hills appear to imply a scenario of gendered social distinctions but not inequality between both, seen that there are phallic representations in panels that picture male initiation and

sex, and vagina representations in panels that picture sex and pregnancy. There is, however, a great amount of what has been named "neutral gender" – human figures without genitalia represented – that made the author works with the idea of a "primitive equality." Additionally, based on contemporary patterns and behaviors, Castro (2010) proposes the absence of rigid *tabus* regarding sexual relationships – using sexual positions and sexuality as synonymous. In sum, such research was responsible for helping to create an evolutionary line that begins with egalitarian societies of hunter-gatherers with a fluid sexuality and transforms itself with the advent of agriculture, when not only female activities are controlled but the female body itself is made object of possession.

The last context we discuss is the ceramics of Marajó Island, located in the mouth of the Amazon River. This elaborate ceramic complex is notable for its elaborate anthropomorphic vessels – especially funerary urns and figurines – and intricate decorations that often incorporate human and animal elements. The relation between ceramic and body construction is evident. For example, bodily representations can include human-like forms with scorpion eyes, serpent-like arms, and a myriad of other motifs. Many of these figures also include sexual features in the form of painted triangular appliqués that represent vaginas, appliques identified as nipples, and many other forms of sexual representation (Schaan 2001, 2003, 2006; Barreto 2005).

In this area, the organization of a complex system of artificial mounds with dams used for fishery, together with the management of cultivated plants such as maize, gave support to interpretations of Marajoara occupations as first evidence of complex pre-Columbian food-producing and matrilinear societies in the mouth of the Amazon from ca. 400 to 1400 AD. The identification of a distinctive pattern in funerary contexts – in which decorated urns containing ceramic "thongs" (known as *tangas* among Brazilian archaeologists) and small ceramic vessels are related to females and non-decorated urns with stone axes inside are associated with males – was used to define Marajoara society as a *Cacicado* where social hierarchies were matrilinearly-based, but only men could be leaders. (*Cacicado* is the concept adopted by several archaeologists to refer to complex and stratified indigenous societies in precolonial times.) Furthermore, Schaan (2003) concludes that social distinctions were primarily based on a hierarchical system of elites and common persons and not between men and women. For instance, Barreto (2005) associates ceramic thongs (Fig. 4) with female ornament (based on its triangular morphology), while figurines that represent feminine elements (i.e., nipple, vagina, womb) through a phallic format (the head and body composing the penis and the legs composing testicles) are interpreted as ritual objects linked to elite and shamanic activities (Schaan 2003; Barreto 2005). (Besides some articles mention the presence of thongs in female secondary burials (Schaan 2008, 2003), there are some contexts where they are associated to masculine burials (Barreto 2005; Schaan 2001). This can suggest that its use can be an allusion to specific maternal lineages.)

Gender and Feminism in Brazilian Archaeology, Fig. 4 Ceramic thongs (tangas) from the Marajoara context (Museum of the Pernambuco state). (Photo: Emerson Nobre)

Those ceramic feminine bodies with their "fertility" features exposed are used to infer the presence of a feminine fertility cult – an Amazonian "Venus" – associated with aspects of prestige and ritual activities (Schaan 2003; Roosevelt 1998). Other paradigms based on ethnographic accounts go beyond this dualistic perspective between men-women/patriarchy–matriarchy/human–non-human to think about the construction of these "bodies of clay." Cristiana Barreto (2005) conceptualizes ceramic vessels as constructed bodies to better approach a more critical perspective closer to the construction of human bodies in indigenous societies. In funerary contexts, the presence of urns with female representations used in both feminine and masculine burials can be seen as an allusion to the cycles of life and a connection between life, birth, and death. In moving beyond strictly functionalist and formal approaches, Barreto argues that decorative motifs on *tangas* could be better interpreted as markers of social associations relating to distinct identities like families and clans (families, lineages, or clans) for both men, women, and children.

In summary, even in these very distinct contexts regarding material culture, localization, and chronology, between archaeological sites from Amazon, Piauí, Bahia and the southern coast, there are strong commonalities in the way that researchers have interpreted gender in this field. Objects like urns, thongs, ceramic vessels, and pictorial representations are directly associated to a sex-gender. There is a tendency in Brazilian precolonial archaeology, where binary sexual dimorphism, sexual division of labor, and gender identity are linked to roles played by men and women through artifacts from funerary and ritual contexts. Gender is not interpreted as an identity, but as a number of activities and conceptions about feminine and masculine sex – even if treated as an extra somatic social construction. Sexuality, otherwise, is far from being a solid theme and for taking into account political and cultural organizations relating to the erotic and to sexual relationships, identities, and politics.

Historical Archaeologies and the Role of Women

Historical archaeology – concerning the expansion of the European world system, the colonial encounters and conflicts and the construction of the Brazilian nation state – has become one of the most prominent spaces for gender discussion in Brazil. Among its main issues, reclaiming the history of women – captives, Afro-descendants during colonial slavery, or free women – is an important political tool to deconstruct the idea that women remain only in domestic spaces. Archaeological studies of the African diaspora in the South of the country (Rodrigues 2015) are framed in a decolonial agenda. In the Imperial Period of Brazil, during the nineteenth and twentieth centuries, the societal position of women is debated in relation to their labour in the countryside, especially in gold-digging activities in the states of Minas Gerais (Ribeiro 2013) and Bahia (Sousa 2006), and in the material culture, acts, and practices of women from the urban elite in the states of Rio de Janeiro (Lima 1995, 1997, 2003) and Rio Grande do Sul (Fredel 2008, 2012).

Tânia Lima (1995, 1997) wrote one of the pioneering works on gender in historical archaeology. Her article about the ritual of tea shines a light on it as a practice imported from the English to the *carioca* elite as a particularly feminine practice, a space where they learned, perfected, and demonstrated their good behavior and elegance. The fine pottery used for tea consumption materialized this practice in nineteenth century archaeological sites in Rio de Janeiro. In such sites, miniature tea faience sets attest to the importance of inculcating bourgeois and middle-class values in children. Through analyses of different types of historical documents and literature, Lima realizes that, besides being a feminine practice, the tea ritual was performed in the living room, a predominantly male place. This ambiguity was part of a new capitalist order that contradicted the traditions of a slave-based, patriarchal, and colonial society. In regards to working class women, Camila Agostini (2010) sheds light on the domestic ceramic producers of São Sebastião, a small town on the coast of São Paulo state. These

pots were made in the nineteenth century primarily by poor white women, though some of the workers were also descendants of slaves brought from Africa. As Agostini notes, it is possible to recognize the activity of these captive women through their choice of decorative patterns that reference distinct male scarification drawings.

In the urban center of Belo Horizonte in Minas Gerais state, Luisa Roedel (2017) highlights a possible burial of a intersex individual at the Bonfim cemetery. Unlike other burials at the site, this particular grave did not a bear a name on its tombstone but instead displayed an inscribed epitaph referring to the famous nineteenth century French intersex, Herculine Barbin (cf. Foucault 1980). It is a plain and unadorned tomb that contrasts with the rest of the cemetery, even though it is located in the area of the cemetery apportioned to important and affluent local families. Roedel suggests that this burial may present a case where a conscious effort was made to erase the individual's identity. Since we know that intersexuality was considered to be a medical condition and gender anomaly during this time, Roedel suggests that this erasure directly links to the suffering this individual would have experienced in life, considering that "hermaphroditism" has been treated as a gender anomaly that needs medical treatment from the nineteenth century onwards. The necessity to choose a dominant sex was (and still is) a violence to intersex individuals, as underlined by the stories of Herculine Barbin and the unknown person at Bonfim cemetery, both of whom were marginalized in life and after death.

The recent period of military dictatorship in Brazil (1964–1984) is discussed by Jocyane Barreta (2017) through the lens of feminism and the decolonial archaeology. She studies the architecture of DOPS building and highlights its design strategy which aimed to degrade the humanity of the inmates. (Social and Political Order Department, which executed illegal arrestment against political militants that were contrary to the military government. In DOPS occurred practices of torture (physical, sexual, and psychologic violence) to take testimony of prisoners, many of whom were buried in illegal cemeteries or throw in clandestine trenches.) For male inmates, the process of dehumanization involved "feminization" through torture involving the sexual organs and the exposure of their bodies in ways to make them appear feminine. Such a distinction of gender in the process of dehumanization through torture of both men and women show that "gender differentiation is embedded in ideological and [the] epistemic logic of colonial modernity, emphasizing the dichotomy and hierarchy of gender" (Barreta 2017: 28).

This movement within historical archeology, as well as the studies of museum collections that highlight the lived experiences of women, serves to foreground the importance of feminine spaces of action in order to better understand the social construction of their bodies, gestures, clothing, and tools (Carvalho 2003, 2008, 2011). A strong criticism of this field is its invisibility of black and subalternal women in the Brazilian history, which is connected to a growing scenario of critical research about the foundations of racism, classicism, and colonialism, all contributing to unveil power structures that have women as agents of resistance. Even when closer to a politically engaged archaeology, researchers expose a historical segregation in the practical making of archaeology or field work: this research is mainly conducted by white men and women. Reflections about gender in historical archaeology have as principle, until now, to make women visible as they have been invisible for centuries, treated as secondary subjects or accessories in androcentric narratives.

Reflections on Archaeology from Indigenous Ethnography

In Brazilian archaeology, especially in Amazonian researches and with ceramist population from several regions (Tupiguarani, Aratu-Sapucaí, Taquara-Itararé, etc.), there is a recurrence in using ethnographic analogies to interpret past contexts. Regarding gender issues, this is basically restricted to assigning certain roles to men and women – ceramist women would be responsible for domestic and agricultural chores and men would focus on producing lithic tools,

hunting, fishing, and in politics. Those stereotypes have some exceptions or variations, but this is the general model (Landa 1999).

Anna Roosevelt has long debated on the origins of social complexity in ancient Amazonian society and its complex political systems (like the *cacicados*) has given weight to the possibility that the social positions and roles of women in these societies may have been more central than those that developed in postcolonial Amazonia (Roosevelt 1991). As noted above, Roosevelt contends that Marajoara society was matriarchal. In a similar vein, Denise Schaan explains the nature of social status in Marajó and Santarém cultures as a class-based system predicated on social divisions between elites and commoners, suggesting that women would have more status. Both scholars also highlight evidence of matriarchal indigenous social orders recorded historical documents written by Jesuit missionaries during the seventeenth and eighteenth centuries. These accounts illustrate the social significance of specific "noble" indigenous women among the Tapajós people of the Lower Amazon, known as "princesses" (Bettendorf 1990; Heriarte 1874).

Such an inversion of indigenous precolonial women role was important to put in evidence – even though through tortuous paths – how the understanding of gender among non-Western groups was constructed. In this sense, Brazilian archaeology is conversant with ethnoarchaeology and ethnographic analogy, but the discussion about gender in ethnology is not incorporated to the same extent, and this theme is not dominant in studies about indigenous people in Brazil. However, another transversal theme about gender that can bring archaeology and anthropology closer is the construction of the body.

Research on conceptions of the body (i.e., animal and human, men and women, children and adult) have played a central role in Brazilian ethnology. It is the *locus* where different personas and agencies are constructed. This construction is given only through specific practices such as food and sexual prescriptions, seclusion, learning techniques of labor and behavior (Seeger et al. 1979). This perspective has a very small impact in interpretations about archaeological remains, as the previously mentioned in the research by Lima (2012) and Roosevelt (1998), in which indication of diet differences are interpreted as *status* and leadership privilege or as hierarchies between male and female children are created in moments of food crisis. The production and (in)differentiation of bodies could very well be the connection point between precolonial archaeology working with indigenous people and anthropological gender theory.

Therefore, gender archaeology in Brazil could/should have a greater penchant to decolonizing debates, in the same way that other types of research do, as part of the production of knowledge is referred to non-Western groups that have very distinctive social forms if compared to the Eurocentric, Christian, and capitalist models. In conclusion, perspectives about gender diversity and identity that are applied in narrative construction about precolonial societies are culturally located and reflect a historically rooted Eurocentric, heteronormative, and masculine effort to colonize native bodies. In the words of Loredana Ribeiro:

> "(. . .) while witches were burned in the Metropolis hearts, in the colonies the Christian civilizatory project was concerned with the mission of transforming non-human males and females (since uncivilized, bestial and hypersexual) into men and women". (Ribeiro 2017: 215).

The Feminist Spring in Brazil

Since 2010, there is a growing academic and politically motivated movement in Brazilian archaeology to better engage with *queer* theory in their study of the past. This feminist-allied theoretical movement can be seen in a wide-array of academic products like scholarly articles, theses, dissertations, etc. There is, however, an eminently political scenario in which men and women – professionals and students – have guided and struggled against chauvinism, homophobia, transphobia, racism, and other normatives in several spaces of archaeology, from the university to environmental licensing, in field works, laboratory, museums, and other institutional spaces.

In political terms, feminist and *queer* activism have frequently occurred in scientific meetings – national and regional – like the Meetings of the Brazilian Society for Archaeology (SAB) in 2015 (18th meeting of the Brazilian Society for Archaeology: Archaeology to Whom? 2015, Goiânia, Brazil), its third northern meeting in 2016 (3rd meeting of the Regional North of SAB: Archaeology and Traditional Communities in Amazonia. 2016, Porto Velho, Brazil), its tenth southern meeting in 2016 (10th meeting of the Regional South of SAB: Deconstructing Asymmetries. 2016, Pelotas, Brazil), among others. In those meetings, men and women public manifestations against chauvinism, homophobia, and harassment suffered daily has exposed not only the actors of injury but also the academic structure itself, beyond the specific case of archaeology. Issues, such as wage inequality, hierarchy in scientific consulting activities, moral and sexual harassment in the field, a nonproportional incorporation of men and women in reference for the educational system (Ribeiro 2017; Passos 2017), among others, are being debated in order to recognize patriarchal influences not only in archaeological theory but also in its practices.

The Brazilian Society for Archaeology has incorporated matters regarding gender, sexuality, class, ethnic, and racial identity discrimination to its ethic code only in 2015, opening a channel for those practices to be exposed. Even so, there is an abyss between what is written on paper and the practice which can only be surpassed by a conscience creation process among professionals and students and a structural change in archaeological science. In the same year, besides the occurrence of a themed session regarding women's role in national scientific production, a political paper proposed to open wide chauvinist and homophobic practices that are crowded in professional archaeology:

> "Archaeology is a social Science, with a practice engaged in the contemporary world. Ours attitudes in the field and with the communities (*with who we work*) influence the construction of archaeological knowledge. The debates created in the academy should be reflected in empiric research, such as in our etic compromise". (Zine 2015).

In the same way, it happened with feminism and *queer* theory in other, mainly English speaking, countries. This critical movement goes from politics to academy and begins to make itself present in Brazilian archaeology. In 2017, the 13th Women's World was held in Brazil together with the 11th Making Gender, in which the session *Excavating Gender: Women in Indigenous History* (coordinated by Juliana Machado) was the first dedicated to this issue in Brazil. While the year 2000 represented a turning point in North America with the publication of *Why Queer Archaeology? An Introduction* (Dowson 2000) and *Archaeologies of Sexuality* (Schmidt and Voss 2000), Brazil had to wait another 17 years until the publication of *Archaeology and Feminist Critic in Brazil* (organized by Ribeiro 2017). The articles published in this dossier, many of them already mentioned in this entry, reflect a ripening of archaeological research and feminist criticism regarding women's knowledge diffusion in diverse themes – from precolonial archaeologies to the archaeologies of present times.

The themes are also more diverse when compared with the classical research described in the first chapter of this article: repression of women in Military Dictatorship (Jocyane Baretta), the construction of gender stereotypes in museums (Camila Wichers), the proposition of an archaeology of sexuality (Fabiano Gontijo and Denise Schaan), misogyny and homophobia in field activities (Frederic Poujet and Aline Carvalho), diffusion and reception of women's production in Amazonian archaeology (Caroline Caromano, Meliam Gaspar, Ester Pereira, Márjorie Lima, and Jaqueline Lima), and in undergrad and grad archaeology programs (Lara Passos) – only to mention those working on Brazilian issues.

In conclusion, there is an interpretative rush relating to forms of comprehending categories of "sex" and "gender," and to the possibilities of putting them in operation in different fields of archaeological research. Beyond a dichotomy between men and women, several forms of fluid and nonhomogenous sex, gender, and sexuality appear as interpretative possibilities and as criticism to the appliance of heteronormative occidental model to the precolonial past of Brazil.

Growing ethnographic production related to indigenous, black, feminist and LGBTQ political movements is added to this process, which complicates the issues of sexual division of labor and its parameter of universal male domination, as it does with issues regarding the construction of person and the correlations between sex and gender.

Queer theory is being pointed to as a powerful tool for producing a more "warned" archaeology, informed about the occidental constructs about gender, sex, and sexuality (Ribeiro 2017; Gontijo and Schaan 2017). From the North American reflection under *Queer* Archaeology and the incorporation of the criticism of using medical-juridical parameters involved in the creation of dimorphism and binary sex and of searching for sexual patterns seen by occidental societies as deviants, the authors propose a research agenda disposed to deconstruct Brazilian archaeology. Dimorphism and binarism, two of the main parameters in classical Brazilian researches, are taxonomies socially constructed to political ends. The intersections between sex, gender, sexuality, class, ethnic-racial identity, age, etc. are alternatives to such taxonomies and archaeology as emancipatory practise – more than a parameter to construct "alternative archaeologies."

Concluding Remarks

Within this patriarchal scenario, Brazilian archaeology carries a historic reproduction of Western categories in its theories, which contributed to erasing nondominant genders and sexualities in the contemporary world and in the precolonial past. In the professional medium, a chauvinist structure mainly occupied by men – professors, research project leaders – is also a place of feminist, LGBT, and *queer* production, which strives to deconstruct gender stereotypes and point to new conceptual and political directions that bound archaeology, whatever the historic period in question.

There is a mismatch between Brazilian and world reflections about gender, feminism, and *queer*. An example is the prominence of big historical-culturalist projects executed in Brazil between 1960 and 1970, a period during which North America and Europe were developing new archaeologies and several postprocessual archaeologies. Feminist and gender debates in the field of history and anthropology in Brazil gained strength after the fall of the last military president, in the so-called "democratic opening" in 1984. It is from this point the social movements in general, including women – black – deviant movements, emerged from clandestinity and begun to branch out to diverse fields occupying professional and educational environments.

What we see in Brazilian archaeology is a conservative and traditional scenario, where not even ethnic (even if indigenous people are main "actors" of "prehistoric" archaeology) nor gender minorities are taken into account. One frequent argument in debates and scientific articles is that "Brazilian archaeology is little developed, and we should invest our efforts in raising data, after all, we have a continental territory". (Today, there are 11 undergrad programs of archaeology and 5 universities with master and doctoral programs in Brazil. The expansion of education system in the last 15 years generated the entrance of profile of students: indigenous, *quilombolas*, black person, and people from urban cities from nonprivileged social and economic classes. In 2017, the first indigenous archaeologist, Jaime Xamen Waiwai, has graduated in Archaeology at the Federal University of Western Pará.) This apparently non-theoric arguments deliberately reiterates an occidental point of view, in which other archaeologies that propose forms of methodology and interpretations about the past – about gender, feminism, or positioned ethnic engagement, as indigenous, black, and subaltern archaeologies – have small relevance to science, bringing more interpretation than empirical data.

Gender, Feminist, and Queer Archaeologies: A Spanish Perspective

Sandra Montón-Subías and Enrique Moral
Departament d'Humanitats, ICREA/Universitat Pompeu Fabra, Barcelona, Spain

Introduction

In the 1970s, in the aftermath of second-wave feminism, feminist scholars identified androcentric sexist biases behind scientific research, which included archaeology. They noticed that both the professional practice and the interpretation/presentation of the past were permeated by values enmeshed in the twentieth-century hegemonic gender system and argued for a culture of equality within the discipline.

In the following decade, Spanish archaeology began to incorporate this critique, led until then by archaeologists mainly working in Norway and the USA. Since then, the momentum gained by a growing number of researchers has turned feminist and gender studies into one of the most dynamic fields of the discipline in Spain, a field in its own right both in the general context of gender and feminist archaeology and in the particular context of theoretical and methodological discussion in the Iberian Peninsula. Also here, feminist researchers have promoted self-criticism and reflexivity within the discipline, provided alternative interpretations to problems previously examined, and developed new fields of inquiry. This has not included, at least until very recently, the queer archaeologies that developed from the end of the 1990s in English-speaking and Scandinavian countries. Because of this, the majority of this entry focuses only on the development of feminist and gender archaeologies, since queer archaeology is a promising but still incipient field in Spain.

Definition

Gender, feminist, and queer archaeologies refer to those archaeologies that explicitly problematize sex, gender, and/or sexuality in interpretations of the past and/or in the present practice of the discipline itself. Feminist and queer archaeologies are politically engaged with the end of patriarchy and, therefore, promote a cultural change in the discipline to remove its sexist and heterosexist biases. The archaeology of gender may have such a political dimension, but this is not always the case – there are both feminist and non-feminist archaeologies of gender. When the political dimension is not present, the archaeology of gender only broadens the content of other interpretive frameworks in considering the sociocultural interpretation of sexual difference as a structural principle in society, therefore adding gender to the study of the past.

Historical Background

In Spanish archaeology, the explicit interest in questioning androcentrism and problematizing questions linked to the experiences and practices of women began only a little later than in the pioneering countries, since the first related paper was published at the end of the 1980s (Sanahuja and Picazo 1989). Since then, the rejection of the double discrimination of women, in the profession and in the explanation/presentation of the past, has promoted a critical review of archaeological practices and narratives, new hypotheses for interpreting and reinterpreting the archaeological record, and new analytical categories for understanding historical dynamics. Currently, the volume of publications is such that there are already compilations that track events until present day (e.g., to mention just a few, Díaz-Andeu and Montón-Subías 2012; Zarzalejos 2008).

As in Norway and the USA, Spain also incorporated these concerns from feminist perspectives. However, both the theoretical-methodological context that received them and the interpretive model behind were different. While in the aforementioned countries processual archaeology already had a lengthy history and the post-processual move was beginning to emerge, in Spain culture history prevailed, being the description of archaeological materials the primary concern. This traditional way of understanding and practicing archaeology was primarily questioned from historical materialism – well-informed, nonetheless, by the processual methodology so popular in the English-speaking world. This early theoretical phase should be understood within the context of the unique political and historical situation of Spain at that time. The Spanish University had just experienced a transition due to the end of the Francoist dictatorship in 1975, and a number of archaeologists engaged in Marxism – and, in the case of some women, feminism too – were recruited into the team (on this process, see Vicent 1994).

For the previous reason, the first feminist archaeologists in Spain were also immersed in Marxist ideology. This union between Marxism and Feminism initially led to the distrust of gender archaeologists in the USA and England, which were seen as examples of historical idealism and low-intensity political practice. From this standpoint the category of *gender* was initially met with suspicion, perhaps even dismissal, and the concept of *sex* was preferred: "relations between the sexes" and "sexual roles," among others, were the expressions in use (Colomer et al. 1993: 5). This explicit wish to differ from gender archaeologies has continued through the years in proposals linked to the Marxist tradition (Vila Mitjà et al. 2017 being the latest), which has sometimes sought bonds with feminism connected to the French and Italian theories of sexual difference (Sanahuja 2002). That is why in Spain, apart from the fact that there are "feminist" and "non-feminist" archaeologies of gender, there are also "gender" and "non-gender" feminist archaeologies.

Despite the fact that in the 1980s interest in gender studies was very minor in Spanish archaeology, it had a significant weight within the group of professionals interested in promoting theoretical debate within the discipline. For instance, one of the sessions of the first and only "Reunión de Arqueología Teórica" (Meeting of Theoretical Archaeology, RAT), held in

Santiago de Compostela in 1992, was devoted to "Arqueología y Mujeres" (Archaeology and Women). This was the first time that the discussion of androcentrism in the discipline, including concerns on the professional practice, was transferred from individuals and specific groups to a wider national academic framework. The session provided much-needed reference for female archaeologists who had personal experience of sexism and spurred interest in the issue. At the end of the 1990s, the first book about archaeology and feminism was published (Colomer et al. 1999). It was a reader with 12 seminal works, mostly produced in England and the USA, but also in Norway, Sweden, and Mexico, aimed at facilitating access to the Spanish-speaking public to some of the most significant contributions in the development of feminist archaeology. It was also at the end of the 1990s when, faced with the ever-growing Anglophonic production and the influence of other disciplines like anthropology or history, the archaeology of gender (strictly speaking, that which incorporates gender as an analytical category) also entered into Spanish academia. The path for feminist archaeologies different to the earlier Marxist ones was then open.

Finally, it was during the first years of the twenty-first century that feminist and gender archaeologies were firmly established in Spain. In this period, the first monographs were published. In the year 2000, for instance, the *Seminario de Arqueología y Etnología Turolense* dedicated the 22nd volume of its journal, *Arqueología Espacial*, to gender and space in archaeology. Furthermore, new gatherings of women in archaeology were organized in different universities. The first was the course "Archaeology and Gender" that took place at Granada in 2003 (Sánchez-Romero 2005). Inspired by the Wedge conference procedure, and its influential *Engendering Archaeology*, this occasion also saw various archaeologists discuss their ways of understanding and practicing feminist and gender archaeology in front of the student body of the university. Soon after, thematic seminars on specific questions, such as "maintenance activities" (see below), held in Barcelona in 2005 and 2007 (Montón-Subías and Sánchez Romero 2008), began to be organized. In 2006, the Museum of Prehistory in Valencia organized the first museum exhibition of women in prehistory (Soler 2006). Originally designed with a provincial character, it soon aroused the interest of other Spanish museums and institutions, generating debates, courses, and circuits of academic dissemination where it was exhibited. In recent years the administrations in charge of some archaeological sites have expressed interest on gender and feminist debates by organizing courses and seminars such as *Women, genders and archaeology*, organized by World Heritage *Dólmenes de Antequera* in 2015, or *Gender and Maintenance Activities*, organized by the Roman site of Camp de les Lloses in 2017. Also in the past few years, queer stances have flourished within Iberian archaeology, thanks to events such as the *XVIII Meeting of Young Researchers in Archaeology* celebrated in 2017 in Vitoria (Basque Country) and devoted to queer and "transfeminist" studies or the exhibition *TRANS**, held in the same year in the Museum of America, Madrid, on the diversity of gender roles and identities within the American continent.

Key Issues/Current Debates

In over 30 years of research on gender and feminist archaeology in Spain, works on diverse themes have been published. Drawing on the critique of androcentrism, concerns similar to those demonstrated first in the pioneering countries have prospered. Thus, we have publications on the work and contributions of women in the past; on the labor situation of female archaeologists; on the sexist of archaeological discourse and language, verbal and nonverbal; on new ways of presenting the past and reflections on fundamental concepts, like those of space, time, and identity; and on new categories of historic analysis (a more detailed examination of those works can be seen in Díaz-Andreu and Montón-Subías 2012). Some of these concerns have been brought together around two specific lines of inquiry that Spanish archaeologists have and are contributing to the global scene:

maintenance activities and the sociohistorical construction of gendered personhood and self-identity (see also Montón Subías and Lozano 2012).

The maintenance activities approach was raised at the beginning of the 1990s by a group of researchers at *Universitat Autònoma de Barcelona* and within the emphasis given by a feminism of Marxist inspiration to the analysis of women's work and material conditions. The proposal was initially aimed at investigating a specific sphere of social production and reproduction, a sphere that had been forgotten in traditional master narratives (including those of Marxism). Soon other researchers joined their efforts. They shared with them concern and dissatisfaction of the sexist biases affecting the practice of archaeology and the motivation to join new categories of analysis to evaluate the practices and experiences of women. Inevitably, many of these contributions, although not all, exceeded the original theoretical framework, adding and/or combining concerns stemming from feminist theories different to the Marxist ones. Currently, this approach continues to be enriched by the contributions of different researchers within and outside of Spain (see, e.g., Montón-Subías and Sánchez-Romero 2008).

The concept of maintenance activities embraces under a single expression all basic activities necessary to create, regulate, stabilize, sustain, and reproduce (in the short, medium, and long term) society's lifeways. Related to the management of everyday life and the well-being of all of its members, they include, grosso modo, caregiving, cooking and food processing, basic textiles, hygiene and public health, the socialization of children, and the fitting out and organization of residential space. Specialized in maintaining the group's social connections and bonds, they are part and parcel of the relational framework in which they take part and which they create. Although chrono-geographically variable in its cultural forms, what remains stable is the structural function to which the term refers to (González Marcén et al. 2008: 4). With slight variations, the study of the previous tasks, in their possible conjugations, is what often appears in the analyses of maintenance activities (see Montón-Subías and Lozano 2012, and Sanahuja 2002: 172–189 for a review of the Marxist perspective).

The approach emphasizes, therefore, the structural character of these activities, whose ultimate function is to guarantee the reiteration and recurrence of the group's activities and/or to channel any changes in the latter into new reiteration and recurrence patterns or, in other words, into new ways of everyday life management (for a wider discussion, see González Marcén et al. 2008). Because of this, it has been unveiled as a tool with great potential to evaluate social dynamics over vast lapses of time and periods considered as transitions (see, for instance, section "Historical Background" in Montón-Subías and Sánchez-Romero 2008). Analyzing daily life in the long run, their forms of permanence and change, allows us to better understand the articulation of the different variables – also those considered macro – that integrate the social fabric, as well as their changes and modifications.

In this already established approach, one of the most recurrent debates has referred to the nature of the association between women and these practices. Do these perspectives homogenize the experience of women and confine them to this unique field of action (Picazo 1997: 60; González Marcén et al. 2008: 3; Lozano 2011: 31)? It is true that the proposal was initially partly aimed at interpreting the experiences and practices of women in an alternative way and that, therefore, there was an implicit link between maintenance activities and practices carried out by women. But already in the initial contributions, it was stressed that their dismissal by mainstream archaeology was due to their association with the female sphere in modern times. Subsequently, their relational character and their recurrent rhythm, in direct opposition to change, individuality, and power -the values highlighted by history, which is the discourse created to legitimate modernity (Hernando 2012)- were added as main reasons in their concealment. In any case, many different works have insisted that the association between women and maintenance activities has a historical genealogy, that women are also found in other realms, and that in

the origins of humankind the whole group would have been involved in their practice.

Indeed, subscribing the perspective of maintenance activities and suggesting that an important part of the times and roles of many women has been overlooked do not mean defending that maintenance activities represent the whole set of (potential) activities carried out by women (in fact some of the professionals that work on maintenance activities also investigate the presence of women in other spheres of action, traditionally assigned to men [Sánchez-Romero and Moreno Onorato 2005]). It does, of course, mean understanding this sphere of action in its singularity and articulating it with the rest of the social, economic, political, and ideological variables that orchestrate the course of life for human societies.

The feminist politics in this line of inquiry is underpinned by reflection on the values that should be integrated in the writing of history and how they might help in building a new form of public rationality. With the inspiration of authors grouped around the "ethics of care," like Nancy Chodorov or Carol Gilligan, unorthodox Marxist authors like Anna Jónasdóttir, and others linked to the feminism of difference connected to the Milan Women's Bookstore Collective such as Luisa Muraro and Adriana Cavarero, emphasis is placed on the value of relationality and interdependence. This endeavor is shared with another of the most original contributions of feminist archaeology in Spain: that which analyzes the historical reasons for gender inequality in the Western world starting from the study of the mechanisms through which we construct self-identity.

This line of investigation, which arose in Madrid in the late 1990s, started from a different point than the majority of feminist studies. It did not initially focus on women, but rather on the way that human beings construct their identity (Hernando et al. 2011; Hernando 2012). On the basis of her own previous ethnoarchaeological work in oral societies and drawing from studies in psychology, sociology, philosophy, and anthropology that had already examined the differences between relational and individualized identity, Hernando suggested that individuality and relationality constitute "packages" of characteristics that are combined in complex and dynamic ways within one single person, depending on their position of power or control in the social group. The author analyzed the genealogy of contemporary gender identities in the Western world, concluding that, initially, all men and women in human societies would have had relational identities (similar, in structural terms, to those that characterize contemporary hunter-gatherers).

This means, according to Hernando, that the so-called feminine identity would not be but the "relational identity" typical of both men and women in the beginnings of humankind, which allows her to escape from essentialisms linked to sex. In accordance with this perspective, men would have been slowly and gradually developing individuality, while women would have maintained the relational identity until modern times. Since then women would have also developed characteristics of individuality, but by virtue of their different historical trajectories, there would be a difference between the current individuality of men and women. Obviously, this line of work was aimed at analyzing the reasons of this differentiation or, in other words, the genesis of the patriarchal order. To this end, Hernando accepted that the extreme fragility of the *Homo* offspring played an important role in the differentiation of identity trajectories between males and females, although unlike other approaches, she did not argue that the central tenet of this differentiation was due to biological factors, but rather to cultural factors related to differential mobility between men and women. Caring for the highly dependent human offspring would have implied travelling shorter distances or less mobility for women than for men. This fact would have been critical in hunter-gatherer societies, considering the vital importance that oral societies place on the spatial dimension in the construction of the world (Hernando et al. 2011). These initial subtle differences in mobility did not establish power relationships between the sexes, but could have constituted the base for a progressive increase of masculine individuality and, with this, the subsequent appearance of the patriarchal order.

International Perspectives

Feminist archaeology in Spain has always shown great interest in knowing debates generated abroad. This openness has led researchers to integrate similar concerns from other countries and to develop strategies to internationalize their own reflections. Out of this, exchanges and collaborations have followed, which make this field one of the most dynamic and international in Spain. These external influences were first expressed through the weight that the "Women the gatherer" movement of US anthropology in the 1970s had in the interest in issues related to the origins of humankind (Querol 2001; Sanahuja 2002). Some years later, in the RAT of 1992, the title "¿Somos todas hombres?" (Are we all men?) was selected to present a paper about sexism in the practice of contemporary Spanish archaeology. It was the recognition paid by a group of Spanish female archaeologists to the first workshop on the subject, *Were they all men,* held in Norway in 1979. Equally decisive was the arrival of *Engendering Archaeology*, published by Meg Conkey and Joan Gero in 1991, that would inspire many later works on feminist and gender archaeology in Spain (see also Cruz Berrocal 2009: 124).

Spanish feminist and gender archaeologies have repaid this initial input bringing to the global scene more examples of how sexist and androcentric values have inappropriately influenced archaeological practice and archaeological knowledge and alternative or new interpretations of an archaeological record that, as a consequence, begins to be much more renowned internationally. The Iberian Iron Age is an outstanding example (Prados and Izquierdo 2006; García-Luque and Rísquez 2008). It has also contributed new analytical categories or perspectives, such as the ones reviewed in the previous section.

This spirit of internationalizing Spanish production has resulted in diverse forums. There have been international conferences in Spain, such as seminars on maintenance activities in Barcelona, which have brought together peninsular and abroad archaeologists to reflect on concrete aspects of the approach (Montón-Subías and Sánchez-Romero 2008). In the same vein, conferences abroad have been attended, including the organization of sessions in the annual editions of the EAA (European Association of Archaeologists) and the SAA (Society for American Archaeology). And publications on platforms of international scope have also appeared (e.g., Cruz Berrocal 2009; Montón-Subías 2010; Lozano 2011; Hernando et al. 2011; Moral 2016a), however mostly in English (in January 2018 only 8 of the 101 journals listed for archaeology in the Thomson Reuters Arts and Humanities citation index were in Spanish). It is important to value the extra effort that this fact implies and the situation of double (or triple, or quadruple) demand faced by many of these archaeologists: on the one hand, to find a way in a national and international academia dominated by androcentric power structures, and on the other hand, to do it in an international academia of Anglo-American hegemony, much more receptive to the empirical cases proposed by Spaniards than the theoretical approaches generated in our language. In fact, by the works cited in the English-speaking world, one could reach the misleading conclusion that there are very few theoretical contributions outside of its own linguistic area.

Furthermore, forums of debate to bring together Spanish-speaking feminist archaeologists from both sides of the Atlantic have also been created. For example, the interest in exploring the relationship between feminism and historical materialism has joined Spanish archaeologists with representatives of the Latin American Social Archaeology (see, e.g., Vargas 2004). A recent example of another Ibero-American (or Americo-Iberian) collaboration is the book *Museos Arqueológicos y Género. Educando en Igualdad* (Prados and López 2017), a compilation of essays written by scholars from Ecuador, Mexico, and Spain that aims to expose the way in which archaeological museums can and must transmit an inclusive history in order to contribute to an education in gender equality. The promotion of multilateral, international contacts is also behind the presence of several Spanish archaeologists in the creation and functioning of AGE, the Archaeology and Gender in Europe working party of the European Association of Archaeologists (http://www.archaeology-gender-europe.org/), a network designed to bring scholars of different

nationalities and academic traditions together in order to develop and exchange information on gender in archaeology in its many dimensions (Dommasnes and Montón-Subías 2012). This internationalist vocation has been in part supported by the Spanish research policy conducted after the Francoist dictatorship in relation to the concession of research fellowships for research residencies in foreign research centers (Díaz-Andreu and Montón Subías 2012). Thanks to these visits, for example, the first news of the influential *Were they all men* and *Engendering Archaeology* reached Spain.

Future Directions

The strength and importance that research on feminist and gender studies holds in Spanish archaeology is established. This said, it should be also clarified that there are obstacles and challenges, both internal and external, for this research. The explicit involvement or the affinity of many of these researchers with feminism and the resulting critique of academic androcentrism, often experienced in first person, cause doubt, reticence, hostility, and rejection in one part of the academic establishment. Without doubt, the progressive popularization of the issue has diminished public critiques, as they would be perceived as politically incorrect. However, from less visible platforms, such as, among others, anonymous decision-making panels, a veiled discrimination may act against research and candidacies related to the investigations of gender; a form of discrimination that is not only more difficult to identify but also more difficult to challenge.

Furthermore, the very dynamic nature and development of this research raises questions that demand greater attention and confront challenges of a different character depending on whether or not the research has a political involvement. A first necessary challenge would be to explicitly clarify the differences and affiliations among feminist archaeologies, archaeologies of gender, and women's archaeologies to avoid conceptual ambiguities. In fact, conceptual ambiguity has begun to happen already within archaeologies of gender. Since the popularization of the issue in the 1990s, some authors have just "targeted" gender, but ignored or rejected its original critical theoretical framework. In these works, gender is no longer a concept but instead a term with which to designate women and, to a lesser extent, also men. By incorporating gender as only a word, one can continue writing about men and women in a conceptual framework that perpetuates stereotypes and gender roles characteristic of the traditional imaginary and from the same androcentric positions confronted initially by feminist and gender archaeologies. Although the original desire of those who devote themselves to gender archaeology from a feminist position was and is to transform the *mainstream*, the opposite effect has oftentimes resulted from "less politicized" approaches. In these cases, the mainstream has transformed gender archaeology, blurring its feminist critique. Still, it should remain clear that in Spain, currently, the majority of the works on gender are elaborated from engagement with feminism.

As in other countries, also here feminist and gender research has mainly been identified with that of women. Indeed, women were the first who drew from their gender stereotypes and expressed the need to find themselves in another way in written history. This being acknowledged, it is however now important to associate feminist and gender archaeologies not only with women, especially when this fact particularizes their study and prevents the understanding of the social and power dynamics of which they are part. While it is important, for example, to continue writing historiographies about female archaeologists, it is even more vital to incorporate women in the general historiography of the discipline. Precisely, to move in this dual field, which is not incompatible, constitutes one of the most important challenges that feminist archaeologies face.

On the other hand, questioning the "hegemonic gender system" from which history has been written also means understanding that men of the past have been constructed following the dominant contemporary model of masculinity, a model which has assigned them a particular way of being and behaving, associated with success, individuality, change, power, heterosexuality, aggression, and violence. But, above all, it means

understanding that the very writing of history has been associated with these values, and oversized activities, such as war, related with them. Despite the fact that in 1998 Thomas Dowson published an article in the 14th edition of the Catalan journal *Cota Zero* calling for queer archaeology (see ▶ "Engendered Archaeologies," this volume) and that the construction of masculinity has become a growing concern in other fields of the social sciences in Spain, this issue has not yet had major impact in the archaeology of our country. For the last years, however, prevailing assumptions related to the hegemonic model of masculinity have begun to be questioned to critically reevaluate the supposedly structural character of warfare and warriors in the Argaric Bronze Age of Southeast Iberia (Aranda et al. 2009). Likewise, some archaeologists have recently adopted queer stances to contest gender and sexual categories in their research, deeply influenced by the Spanish "transfeminist" movement (see Higuero 2015; Moral 2016a, b).

As occurs in other countries, feminist archaeologists in Spain also should reflect more upon the implementation and the implications of their political involvement in archaeological practice. Building a new disciplinary culture should imply awareness and change of the different forms that patriarchal power structures adopt (in field work, in the teaching of the discipline, in PhD supervision, in academic management, or, among others, in the nature of the links with nonprofessional communities interested in archaeology (on this last aspect, see Gonzalez Marcén 2005). Otherwise, we run the risk of modifying archaeological discourse – the most visible front – but perpetuating an androcentric structure through the gears of its production.

Gender, Feminist, and Queer Archaeologies: Australian Perspective

Cherrie De Leiuen
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Gender, feminist, and queer archaeologies in Australia, as elsewhere around the world, are represented by a multiplicity of approaches and individual experiences. The progress of their development can, however, be traced to the emergence and influence of feminism and the women's movement. They are linked by a concern with examining the social construction of gender and its representations, ideologies, identities, and other such manifestations in the archaeological record. Uniquely Australian political and institutional settings have also impacted the evolution and outputs of gender, feminist, and queer archaeologies in this country, in combination with theoretical and research progress in these areas of archaeology globally.

Definition

Feminist, gender, and queer archaeologies are commonly associated together as they examine the social construction of gender and their materialization in the archaeological record, but are not mutually exclusive. They have also been grouped together under post-processualist archaeology. Feminist archaeology critiques androcentric interpretative biases and validates the place of women, either as subjects of study or as practitioners in archaeology. It also concerns the need to examine gender roles and inequalities within the archaeological profession and how this impacts on archaeological theory and method. Feminist archaeology also takes a political standpoint and often examines power relations.

Gender archaeology can be differentiated as an approach which foregrounds gender (which is the socially constructed conception of women and men, not biological sex), with other social categories, such as class, age, ethnicity, religion, and kin. It can also be practiced within a nonfeminist framework and may examine the relative positions of men and women in relation to each other and how these manifest archaeologically.

Queer archaeology challenges heteronormative interpretations by seeking to take the perspective of marginalized sexual, intellectual, or cultural groups. It is not concerned only with homosexuality; rather it presents alternatives to mainstream archaeological discourse.

Historical Background

A distinctively Australian archaeology developed in the 1960s and 1970s (see Colley 2002). Prior to this time it was possible to study anthropology and the archaeology of other continents, but it was during this period that Australian archaeology was first taught at Australian universities, and theory and method were modified for Australian conditions. Fieldwork was essential in providing archaeological evidence for environmental and cultural diversity and in growing an understanding of the antiquity of Indigenous occupation as well as increasing the number of recorded sites, including those resulting from post-European contact. Explanations of the human past were framed in terms of environment and technology, and cultural materialism was the dominant theoretical framework (Huchet 1991: 44). A strong processual platform still characterizes Australian archaeology. This backdrop of disciplinary culture is essential in understanding the development of feminist and gender archaeology in Australia as it has been characterized as distinctively male (see Smith and du Cros 1995; Smith and O'Donnell 2006; Moser 2007). Moser observed: "With its connections to colonialism and penetration of the frontier, fieldwork has been instrumental in attributing archaeology a masculine status" (Moser 2007: 251). Thus, a dominant theoretical setting which de-emphasized social archaeology and human agency, combined with a masculinist subculture of fieldwork, left little room for a feminist or gender archaeology to penetrate the mainstream research agenda. Indigenous archaeology had been further complicated by a Western and male bias towards perceived men's activities in complex Indigenous social and knowledge systems, such as hunting and stone artifact manufacture, often laden with assumptions about the meaning and universality of gendered task attribution. Despite this, research on women's and men's roles had been undertaken, but work had not come together under the umbrella of any theoretical or professional association. For example, as early as 1939 Phyllis Kaberry recorded women painting rock art and their roles in economic systems and information exchange in Northern Australia (Kaberry 1939). Women such as Judy Birmingham, Sandra Bowdler, Isabel McBryde, Betty Meehan, and Sharon Sullivan played a critical role in the formation of the discipline in Australia, but gender was not fostered as a legitimate research area until the 1990s.

In Australia the response to a gender and feminist archaeology is distinctive yet follows the path of similar academic traditions in Europe and North America. Although the first feminist and gender archaeology emerged from Scandinavia, Margaret Conkey and Janet Spector's 1984 paper *Archaeology and the Study of Gender* can be credited as the watershed article globally. Being in English it is still widely cited and can be seen as the first influential summary of the feminist critique of the discipline in Australia. Outside Australia feminist archaeology enjoyed an earlier emergence and greater support among the archaeological community. The 1989 Canadian Chacmool Conference, where overtly feminist papers were presented in conference symposia and published in the *The Archaeology of Gender* (1991) monograph, was undoubtedly an influence which led to the first meeting of the Women in Archaeology Conference in Australia in 1991. The attendance of international keynote speakers Margaret Conkey, Joan Gero, and Alison Wylie aided in the perception that gender was a legitimate research area, and their presence assisted in garnering support for an Australian

agenda. Thus, the 1991 Women in Archaeology Conference is highly significant with respect to research on gender in Australia. It was a turning point for gender as a field of study in Australian archaeology. It reflected both a broader change in Australian society about gender roles, national identity, and workplace rights and a change in the research directions for archaeology. This conference triggered formal discussions of gender and feminist archaeology and legitimized research interests and groups, generating five subsequent conferences and three published monographs (see du Cros and Smith 1993; Balme and Beck 1995; Casey et al. 1998). Much later in 1998, the first session on gender was held at an annual conference of the Australian Archaeological Association.

Key Issues

The key issues and influences to have emerged in Australia can be seen to pertain to two main areas of research. First there are issues of professional identity, equity, status, and the employment of women in Australian archaeology which are linked to personal and political motivations. Second there are issues relating to the establishment and recognition of gender in the archaeological record and, further to this (but to a lesser extent), the development of distinctive Australian feminist theory and interpretation. Queer archaeology has had the least impact of the three standpoints in Australia in terms of publication and influence.

Of the small number of published articles on gender or with a feminist perspective in Australia, the majority are thematically on women's status as archaeologists, not gender, queer, or feminist theory, or on women as subjects of archaeological enquiry (e.g., Bowdler and Clune 2000; Smith and Burke 2006; O'Connor 2008). As such, it is difficult to distinguish the influence of gender archaeology from that of the broader impacts of the women's movement. However, it can be surmised that women may have felt marginalized or a sense of inequity in the archaeological workforce or perhaps experienced personal discrimination. This is likely to have been the initial impetus for research and publication directed into this area, as has been the case internationally (see Nelson et al. 1994). It is also an indication of the nature of the archaeological workforce in Australia where there has been some degree of segregation; most women archaeologists have worked in consulting and cultural heritage management (CHM) and few in senior research or academic positions (with women clustering in lower paid and lower status positions). This is echoed in a study undertaken by du Cros and Smith (1995), who found that it was workplace issues, such as inequity or discrimination, rather than a theoretical standpoint or familiarity with feminist literature, that prompted most participants to attend the first Women in Archaeology Conference in 1991. As recently as 2007 Stephanie Moser has argued for the existence of a hegemonic (heterosexual) masculinity in the discipline in Australia, perpetuated through the subculture of fieldwork. In a 2006 study Smith and Burke found that there were systemic barriers to women's progress in academic archaeology. They found that there was what they term a "two-tiered glass ceiling" where women are less likely to gain entry level and tenured positions into academic archaeology. Of those who have obtained tenure at universities, they were underrepresented in senior positions. Bowman and Ulm (2009) have investigated the disparity between men and women's success in obtaining project funding. Their analysis of 2001–2008 Australian Research Council (ARC) grants found a link between the sex of the funding panel members and the sex of the successful applicants. They also found that more men receive fellowships than women, despite more women undertaking research. This means that women are disadvantaged as early career researchers in Australia; the majority of research is undertaken by women, but the majority of funding is going to the minority, who are men. Though overt discrimination has diminished in recent years and women have made up the majority of the paid archaeological workforce in Australia, they are still not breaking through the proverbial glass ceiling.

In terms of perspectives on homophobia, there is silence on the issue in Australian publications – not because the problem does not exist but, as

writers such as Dowson (2000) have pointed out, because there has perhaps been a need for professionals to downplay their sexuality to maintain authority and/or shield themselves from discrimination. Australia has a history of repression of homosexuality in society largely until the 1990s. Postmodern feminist theory since that time has influenced theories and gender research on sexuality, as well as masculinity in archaeology. A postmodern approach to researching historic masculinity/ies was advocated by Knapp (though not an Australian archaeologist) at the 1995 Australian Women in Archaeology Conference, and archaeologists such as Casella (2000) have demonstrated the validity of interpreting female homosexuality on Australian historic sites. A heterosexual hegemony, however, remains unchallenged in the archaeology of Australia's Indigenous past. This is because Australian archaeologists rely heavily on ethnographic information to complement interpretations of Indigenous archaeologies. Indigenous Australian social and kinship systems operate in terms of male–female relationships, and traditionally homosexuality is a "taboo" topic, presumed not to exist or remaining unquestionable in many communities, as well as the added dimension of men's business/women's business and sacred-secret knowledge (whereby particular customs, rituals, and practices are undertaken by men and women separately [see Smith and Jackson 2005]). Men and women have separate systems of meaning, and these can also be public or private. This is further complicated as Australian archaeology has largely not come to grips with the notion of sex and gender as spectrums rather than as binary male/female dichotomies. Queer archaeology can potentially fill a gap in analyses and be applied to a range of sites by potentially asking new questions (not only in terms of homosexuality), which may in fact be complementary to Indigenous perspectives, and encouraging archaeologists to think "outside the box" of Western and male perspectives.

Dominant models and narratives of Indigenous occupation have failed to move beyond male – female dichotomies. In 1990 Wendy Beck and Lesley Head pointed to the lack of Australian prehistorians moving beyond simplistic male and female assignment of gender to material culture, for example, continuing to identify stone artifacts with males and shell middens or seed grinding stones with women, rather than challenging the idea that a prehistoric division of labor existed. They state, "...there has been little systematic feminist influence on either theory or methodology in Australian prehistory" (Beck and Head 1990: 41). Given the minimal output of work in the area of gender prehistory to date in Australia, it is apparent that there is still a reluctance to move beyond evidence derived via natural sciences and "safe" interpretations of hunter – gatherer societies and male – female dichotomies based on ethnography. There has been some work directed towards reexamination in the areas of stone artifact use, manufacture, and hunting, whereby women making stone artifacts are often dismissed as exceptions. The groundbreaking article in this respect was by Bird (1993), who evidences women's manufacture and use of stone artifacts across Australia and New Guinea. For example, in the western desert of Australia, women used stone artifacts for woodworking and meat cutting, including the manufacture of bowls, digging sticks, fighting sticks, and flake scrapers. As well as differences in use, the raw materials selected also differed from those selected by men. Bird demonstrated that women could and did make stone artifacts; men's and women's technology is organized differently, but it should not be presumed that women were less skilled at manufacture than men. This area of research exemplifies much of the work on gender in Australian archaeology. It still focuses on making women "visible"; to date the majority of analyses have been concerned with establishing the mere presence and contribution of women. It is also important to note that publication in this area has decreased since the 1990s.

Rock art is an area where some contribution has been made to the consideration of gender as archaeologically significant. Rock art is found in all environmental zones of the continent, with examples of Pleistocene antiquity, although most sites are dated to the Holocene. Early ethnographic research had assumed that only men were responsible for its production. This was

disputed by Smith (1991), who collated a number of ethnographic and archival examples from regions of Northern Australia. She contended that gender was a variable that needed to be factored into rock art interpretation; that rock art may have been produced by men, women, and children; and that it may encode information on the age and gender of the artist. Likewise, McDonald (1992) systematically challenged the androcentric interpretation in several papers, while providing evidence that men, women, and children had a role in the stencilling of hands and implements in an analysis of rock art and excavated material. Such studies have permeated the study of rock art and led to a recognition of both genders in art production. Despite ethnographic records which indicate men are responsible for most rock art in recent generations, the contexts of production over thousands of years are most likely to have been much more diverse.

Several studies have sought to reassess the interpretation and assumptions made in terms of sex and gender of human remains held in museum collections. Donlon (1993) found that in the sexing of human remains held in the Australian Museum, there was systematic bias in the attribution towards males, particularly those from the Pleistocene and early mid-Holocene. This may be explained by differences in male and female burial practices or simply the bias of researchers. Hope (1998) also found bias in interpretations of Indigenous burials in Southern Australia. In a similar fashion, McCardle (2002) found that Indigenous bark burials of the Central Queensland Highlands included both sexes and all age groups, which contradicted prior researchers who had assumed these types of burial were only for young men and children.

Historical archaeology was first taught in Australia in 1974 at the University of Sydney, and Judy Birmingham is accredited with being instrumental in its development. With its links by way of British colonialism and European invasion of an Indigenous population, Australian historical archaeology is similar to that practiced in the United States. Although potentially able to provide more detailed social perspectives as aided by text, pictorial, and other evidence, gender is often left to a few sentences together with ethnicity and class and, like Indigenous archaeology, is practiced with a processual focus. As discussed by Lydon (1995), the influential Birmingham and Jeans (1983) model had less to say about social structures than economic and technological ones and was highly androcentric. Though historical archaeology has progressed since the Birmingham and Jeans model, the main focus in the areas of gender to date has been the construction of gentility (Russell 1994; Young 1998), the status of women (Hourani 1990), identifying women in male dominated spheres such as mining, whaling, and frontiers (Lawrence and Davies 2010), and more general issues of cultural identity (Lydon 1999; Ireland 2002). In maritime archaeology, which has undergone significant growth in Australia over the past two decades, there has also been a technological focus, but some work has been directed into the nuances of social relationships (Staniforth and Lawrence 1998). While the complex nature of the relationships between such phenomena as social organization and spatial organization has been recognized and addressed theoretically and despite papers which identify women in the archaeological record, there has been no substantial development of a particularly Australian feminist framework. The significant body of feminist theory developed from the United States has established a context for historical (and Indigenous) archaeology into which gender and feminist theories can be integrated. A reluctance to include such theoretical perspectives is perhaps a reflection of the passive opposition to gender and feminist archaeology in Australia. In a similar sense, a shunning of a feminist "heritage" and theory, in favor of a post-processual narrative, or a mere change to gender neutral language, can be interpreted either as taking a "safer" option or as an attempt at some degree of political correctness.

International Perspectives

One of the major research questions for archaeologists working in Australia is the timing and means by which Sahul (and hence the continent

of Australia) was first colonized by humans and the origins of those humans. Theories on colonization in this region are distinctive, following the argument put forth by Davidson and Noble (1992) that the maritime colonization of Australia must have been linked to people with language and therefore probably constitutes some of the earliest evidence of modern human behavior. Research of this nature thus continues to generate interest and contribute to debates of international significance. There is consensus that the first colonization was by anatomically modern humans and is central to understanding human evolution. Balme and Bowdler (2006) have put forth an argument for the role of gender in the colonization of Australia. While the binary assumptions and universalizing regarding gender that serve as the basis of their arguments are likely to be flawed, Balme and Bowdler nevertheless raise important considerations about the role of gender in such processes as colonizing new lands, an area where discussions on gender or women as active participants in this process is traditionally absent.

An internationally significant study also undertaken in Australia is that by Casella (2000) (although not an Australian archaeologist herself). Gender, sexuality, and power were strong emergent themes in her analysis of networks of black market exchange throughout the inmate population at the Ross Female Factory, a nineteenth-century Australian colonial prison for transported British female convicts in Tasmania. She concluded that both material objects and sexual encounters fuelled systems of illicit barter by relating the differential distribution patterns within the button assemblage to sexual dynamics of the convict black market. Asking and testing whether same-sex relationships can be archaeologically interpreted has highlighted the validity of asking such questions in these environments and demonstrated how a rigorous and gendered archaeology can be produced.

Future Directions

Despite efforts to construct and include gender theory in Australian archaeology, few methodological or theoretical breakthroughs have occurred in any mainstream sense. This lack of progress is due to several factors, including the issue that fundamental terms such as gender, sex, and queer have been used inconsistently and are often used interchangeably, which indicates a negligence in theoretical understanding or interest. This has also led to a misconception that all studies in these areas are concerned with the conflation of the status of women. The notion that gender is invisible archaeologically also persists – especially in relation to Indigenous women and the archaeology of deep time. Such archaeology is largely thought only to be accessible through perishable, organic ("gatherers") material remains or other invisible social processes. There is also, perhaps, a reluctance to consider gender in isolation from other social categories, such as ethnicity, particularly in historical and maritime archaeology. Despite some of the aforementioned work and given the distancing of much of gender archaeology from feminism, the discipline in Australia is *still* in the process of "adding women" (proving their existence) and thus has only achieved what Engelstad (2007) refers to as simply a "cosmetic change" to our interpretations of past societies. In this sense distancing gender from the political, and from theorizing, even within the gender archaeology "camp" may have contributed to the decline in inclusion and relevance in publications over the last decade in Australia.

To clearly delineate a future trajectory for such archaeologies, it is necessary to acknowledge that gender, queer, and feminist archaeologies do have a history and a "tradition" in Australia. Though this may be short and small, an agreed "version" of events, a recognition of an Australian discourse, may in fact prompt archaeologists into generating further discussion or regain the traction that was lost at the end of the 1990s. What is needed is an acknowledgement of those who worked so hard in these areas in the past and new ways to inspire the younger generations of conservative Australian archaeologists to recognize that there is still much more work to be done. These issues could be addressed in future by the creation of new communities as occurred through conferences in the past. The inclusion of the

theoretical aspects of gender, queer, and feminist archaeologies in teaching at undergraduate level at universities within mainstream archaeology, as was done in the 1990s, would also provide opportunities for greater understanding and debate. Following Bowman and Ulm (2009) it can also be asserted that individuals lack the capacity and/or funding to undertake directed research or publish on gender archaeology, as this is an area that has seen a decline in interest and attracts fewer funding opportunities. This is a problem not easily addressed, and not one confined to this discipline.

Australian archaeology has moved forward in developing some aspects of feminist archaeology, such as equity in employment opportunities, and removing overt discrimination. Despite its promising development, particularly in the 1990s, the future of an archaeology of gender (and especially of feminist archaeology) in Australia is uncertain. Given the recent focus on job and fieldwork training, the emphasis on "testable" data, combined with the general apathy towards feminism, and a major focus on CHM employment particularly in areas where mining is being undertaken, most archaeologists in Australia will never work in a university or pursue a higher degree. With a small pool of academics as compared to other countries, the percentage of the archaeological population who could focus on gender is small compared to the proportion who will earn a living from never having to do it. The question must be asked, does feminist, gender, and queer archaeology have a future in Australia at all?

Gender, Feminist, and Queer Archaeologies: European Perspective

Liv Helga Dommasnes
Cultural History Collections,
University of Bergen, Bergen, Norway

Introduction

In some European countries, gender archaeology started as early as the 1970s; in others the first gender-related research projects have yet to be created. Thus, there will be considerable differences within Europe regarding the interest in and development of the field, and it seems right to

speak of European gender archaeologies in the plural rather than one monolithic gender archaeology. On the other hand, the interaction between the different approaches, gender, feminist, and queer archaeologies has been so close that treating them separately becomes meaningless.

In this entry, the historical development of European gender archaeologies will be traced in terms of four distinct regions, each defined by common traits in language and academic culture: Scandinavia, the British Isles, the German-language area, and the Mediterranean region. Central and Eastern Europe would be a fifth region. Gender archaeology here is still in an early stage, however, and will only occasionally be referred to. Chronologically, the discussion will be restricted to prehistoric and early medieval archaeology, following regional definitions. A European perspective is understood as archaeology by scholars working in Europe and dealing with the European past. Nevertheless, there will be a bias toward Northern Europe, the region best known to this author. Within North Europe more attention will be paid to Scandinavia and the German-language area than to the United Kingdom and Ireland, simply because Anglophone European gender archaeology has been addressed extensively elsewhere (Gilchrist 1999; Sørensen 2000; Whitehouse 2006). Spanish gender archaeology is addressed in a separate entry in this encyclopedia (▶ Gender, Feminist, and Queer Archaeologies: A Spanish Perspective).

Overviews of European gender archaeology have been presented in two recent papers, by Whitehouse (2006) and by Dommasnes and Montón-Subías (2012). While the first study is organized by categories of evidence and discusses almost exclusively Anglophone research, the second presents a chronological/thematic discussion of four different European regions, referring to literature both in English and local languages.

Definition

"Gender archaeology" is often used as an umbrella term for several related but separate approaches:

Studies of women in the past (women are the subjects of study)
Archaeology that investigates past societies, including gender arrangements, based on feminist theory, critique, and epistemology (defined by its theoretical approach, feminist archaeology)
Analyses of gender and gender relations in past societies (gender as an analytical category)
Masculinist archaeology (still in a nascent stage)
Queer archaeology (investigates difference, sexualities, and the character of gender)

A common factor in these approaches is the inclusion of gender as a central element of social structures. All modern gender archaeology presupposes problematizing gender as a social construct, rather than taking it for granted, and analyzing the consequences of different gender arrangements. Studies focusing on women or gender without problematizing the concepts are sometimes termed gender-*relevant* research.

Historical Background

General Overview

Gender has been one of many aspects considered in interpretations of archaeological material from the early days of archaeology as an academic discipline, in the sense that artifacts have been ascribed to men and women, respectively.

Modern gender archaeology, going back to the 1970s, was from its inception firmly based in the second wave of feminism. European archaeologies were, at the time, overwhelmingly culture historical or processual (see the entry in this encyclopedia entitled ▶ "Processualism in Archaeological Theory"), and "science" was considered to be objective in the sense that it should be unbiased. In archaeology, feminism therefore became an early introduction to the idea that scholarship could, and should, be value-laden.

The invisibility of women in archaeology and in the past was considered to be a central problem and as a result early feminist archaeology was to a certain extent simply an archaeology about

women. But it was soon realized that feminist approaches must dig deeper. Challenging basic concepts, epistemologies, and practices became one of the hallmarks of feminist scholarship. Sex essentialism was rejected, while gender as a social structure was considered to be a pervasive element of any society. Asymmetrical power relations between men and women were seen to be part of most gender systems, and gender roles were conceptualized as social constructions which had to be investigated within their specific cultural contexts.

Post-processual archaeology, emerging in Europe from the early 1980s onward, brought new impulses from the social sciences and humanistic scholarship as well as an increasing emphasis on cultural diversity in the past. Diversity also became a key word in later developments of gender archaeology, largely inspired by third-wave feminists who were critiquing, often from black, lesbian, or third-world points of view, the monolithic constructions of femininity and masculinity prevalent in previous feminisms.

In spite of the fact that men and masculinities have sometimes been explicitly addressed in post-processual archaeology, the scholars involved do not necessarily think of themselves as gender researchers (Treherne 1998). Masculinity theory and masculinity studies as such have so far been very rare in European archaeology. In a paper advocating the development of a masculinist archaeology inspired by feminism, Knapp (1998: 94) distinguishes between *reactionary masculinities* and *motivated masculinities*. Motivated masculinities are influenced by feminist research and problematize masculinities in much the same way that femininities have been investigated. In a few cases, studies of masculinity are undertaken by women, from a feminist standpoint.

In the context of archaeological gender studies in Europe, postmodern deconstruction of the concepts of sex and gender has emerged as a dominant approach to gender studies, an approach that does not focus on women only. Postmodernism in archaeology has tended to favor the study of individuals, constructed identities, and personhood rather than groups, societies, and systems. In this process, focus in the sex/gender dichotomy has moved from gender to sexuality and embodiment, paving the way for queer archaeology, which can basically be described as an archaeology of difference and in this sense includes anybody and anything that does not fit into the society in question. In a narrower sense, queer archaeology is understood as investigation into genders and various sexual identities in the past. The impact of queer archaeology (in the narrower sense) in Europe has so far been limited mainly to the United Kingdom. A Scandinavian study of gender and the role of the main god Odin in Old Norse religion and ideology is based partly on queer approaches (Solli 2002).

The many approaches sketched above now exist side by side in gender archaeology, globally and in Europe. In sum, gender research is still developing and is characterized by critique on the one hand and theoretical eclecticism on the other.

Chronology: Where and When

Scandinavia, and particularly Norway, seems to have been the first place where a new feminist-inspired archaeology took hold, in the early 1970s. The inspiration was derived mainly from two sources, the critical theory of the German "Frankfurter school" and second-wave feminism from Simone de Beauvoir to American standpoint theorists.

The first Scandinavian gender archaeology initiatives took place among students in the early 1970s and were related to equity issues. A Norwegian conference organized by teachers and museum curators, "Var de alle menn?" (*Were they all men?*), followed in 1979. In 1985 the organization K.A.N. – *Kvinner i Arkeologi i Norge* (Women in Archaeology in Norway) – was founded. Its concomitant journal became the main publication venue of gender archaeology in Scandinavia until it was discontinued in 2005. Thus, critical theory and feminist/gender perspectives had already become part of Scandinavian archaeology when British post-processualism became a strong force in international archaeology during the late 1980s.

British gender archaeology, on the other hand, developed in parallel with post-processualist

approaches. Again, the gender initiative came from students who dedicated a whole issue of *Archaeological Review from Cambridge* (Arnold et al. 1988) to gender issues. In addition to presenting prehistoric women and discussing feminism as a basis for archaeological interpretations, gender as an analytical category was now introduced. In the following decades, this was going to become one of the most influential approaches of British gender archaeology.

Language is probably the reason why the vast amount of German-language gender archaeology, steadily increasing in volume from its inception in 1988 and addressing a wide variety of topics, is little known outside its own (large) linguistic area. Like in Britain, German gender archaeology developed from student initiatives (Mertens and Koch 2005). The German-language archaeological tradition in the 1980s was strictly culture historical and processual but also deeply influenced by neighboring humanistic disciplines. Early gender-relevant inspirations varied from popular engagement with the idea of matriarchies in the past to gender constructivism (Julia Koch 2011, personal communication). The *Netzwerk archäologisch arbeitender Frauen* (FemArc), which was to become the focal point of much German-language gender archaeology, was founded in 1991. FemArc now publishes a newsletter for its members and a book series, *Frauen- Forschung- Archäologie*, on the renowned Waxmann Verlag.

As a whole, southern Europe has so far shown relatively little interest in gender archaeology. Spain is a special case, with a strong tradition of women's and gender archaeologies going back to the 1980s and addressing many different issues (Sánchez Romero 2005; Prados Torreira and Ruis López 2008) (see also the entry in this encyclopedia entitled ▶ "Gender, Feminist, and Queer Archaeologies: A Spanish Perspective"). During the 1990s, a new and innovative strand of gender archaeology emerged from the basis of Marxist and feminist standpoint theories. This "maintenance archaeology" examines small events and the routines of daily life as part of social structures, often reevaluating their importance for the well-being of society and technological and political progress (Goncáles-Marcén et al. 2008).

As mentioned above, gender archaeology in Eastern Europe is still in its early stages, depending on a few active scholars. Until recently, gender archaeologists based in their East European homelands tended to work within processual paradigm exclusively. Changes are on the way, however, thanks to scholars working from within their local archaeological traditions and also contributing to theoretical developments (Berseneva 2008, 2010a, b; Palincas 2010, 2013, 2015a, b).

The chronological sequence presented here also indicates a process of diversification and specialization where different regions have been taking leading roles at different times. The golden years of Scandinavian gender archaeology were from 1985 onward, with a clear focus on feminist approaches. Later on, British (and American) gender archaeology took on leading roles internationally, developing gender as an analytical tool and anthropologically inspired approaches to past genders, respectively. At the same time, a German-language gender archaeology strengthened its position in its own cultural area, combining detailed analyses of archaeological finds with new theoretical impulses. At present, the Spanish development holds promises for a future archaeology where gender and daily-life activities are included in the study of social structures, history, and development, while the emerging East European participation in the gender project opens new horizons for all of us.

Key Issues/Current Debates

In a historical perspective, gender and feminist archaeologies are mainly associated with the study of women and the relationship between women and men. This is now slowly changing as queer and masculinist archaeologies are emerging.

It should also be mentioned that in a European setting, the archaeology of childhood has been closely associated with gender archaeology. Two early papers (Lillehammer 1986, revised and enlarged English version Lillehammer 1989;

Sofaer Derevenski 1994), published in the K.A.N. journal and the *Archaeological Review from Cambridge*, respectively, focused on how to identify children in the archaeological record. In tune with the development of gender archaeology proper, interest has since moved from visibility to the question of children's roles in prehistoric societies and relations between children and adults (e.g., Moore and Scott 1997; Röder 2002; Sánchez Romero 2004; Berseneva 2008). A recent contribution is a large anthology on Mädchen in Altertum/Girls in Antiquity (Moraw and Kieburg 2014). The archaeology of children is now recognized as a separate field represented all over Europe and is organized in the Society for the Study of Childhood in the Past (http://www.sscip.org.uk/).

In the following section, primary issues will be discussed against the background of goals and aims of early gender archaeology. Early publications and the agendas of the two gender archaeology organizations founded in 1985 and 1991, respectively, will provide keys to what was deemed important at the time.

The edited volume *Were they all men?* (Bertelsen et al. 1987), one of the very first volumes in English dedicated to gender archaeology, presented papers from the abovementioned Norwegian conference held in 1979. The editors stated that their aim was "identifying individuals in a prehistoric context" but also acknowledged their debt to the feminist movement which "may have provided a better basis for viewing not only the present but also the far past with a feminist perspective in mind," and the table of contents reveals that focus was almost exclusively on women (Bertelsen et al. 1987).

K.A.N. (*Kvinner i Arkeologi i Norge*, Women in Archaeology in Norway), the organization founded by Norwegian women archaeologists in 1985, presented its aims and goals in the first volume of its journal (published in Norwegian [English from 1996]) by the same name:

To promote well-established research on and by women in archaeology
To present traditional research areas as well as new aspects of research into prehistory
To be a medium for archaeologists seeking a qualitatively new research strategy through the development of new theories, reassessment of methodological principles, new ways of evaluating sources, and search for new source material
To be a medium of thoughts and opinions on the working conditions and the work of women in archaeology and in society

In the United Kingdom, the editors (Arnold et al. 1988: 2) of the 1988 "Women and archaeology" volume of *Archaeological Review from Cambridge* argued that the subject of women in archaeology demanded a critical evaluation of the following points:

The conditions under which women work in all areas of archaeological practice
How women are portrayed in the interpretation and presentation of the past
What gender is and what epistemological questions an archaeology of gender forces us to recognize in terms of social theory

The German FemArc organization (founded 1991) presents its aims and goals on its English-language website (http://www.femarc.de/) like this:

Create contact between women who are involved with archaeology and its related fields.
Prevent the isolation of female archaeologists.
Encourage the exchange of experiences between women.
Improve the employment situation of female archaeologists.
Promote the discussion between archaeologists and other academics involved in women's and gender studies.
Establish an interdisciplinary approach between female archaeologists, scientists of other fields, and interested amateurs.
Expand the theoretical foundations for feminist archaeology.
Open feminist archaeology to the public and to all women.

Establish feminist archaeology and gender studies as themes and methods in archaeology.

In slightly different terms, these declarations of intent all agree on three areas of concern: equity issues, the ways that women had been presented in archaeological narratives, and theoretical approaches. These three issues have been constant companions to gender and feminist archaeologies ever since.

Equity Issues

Equity issues were one of the main issues of second-wave feminism. Equity issues which have been addressed in archaeology include:

The number of women archaeologists and women working in archaeology
Positions held by women in archaeology
Research fields dominated by women and men, respectively
Archaeological arenas (research, teaching, museum, excavations) dominated by women and men, respectively
The prestige of women-dominated research fields

Research carried out in the 1980s and 1990s shows that in some countries, women made up a fair proportion of the archaeologists, but even so, few held permanent positions and even fewer held top positions. Power and prestige followed the subfields or arenas where men dominated. The number of women professionals in archaeology is now increasing all over Europe but gender inequality is still a serious problem in many European archaeological communities. As for gender archaeology, this is still dominated by women.

Learning about the history of women in archaeology became part of equity research. An edited volume *Excavating Women: A History of Women in European Archaeology* (Díaz-Andreu and Sørensen 1998) addressed women's contributions to archaeology in many European countries. Similarly, the FemArc publications *Eine Dame zwischen 500 Herren* (Koch and Mertens 2002) and *Ausgräberinnen, Forscherinnen, Pionierinnen. Ausgewählte Porträts früher Archäologinnen im Kontext ihrer Zeit* (Fries and Gutsmiedl-Schümann 2013) present portraits of female pioneers in the German-language area.

Representations of Women and Gender

It is only a short step from noting the asymmetrical relationship between female and male practitioners of archaeology to asking if this would also have affected the interpretations of the past.

Rock Art and Other Depictions

Past depictions of women, varying from statues to embroideries and rock carvings, were particularly important in early women's archaeology, as part of the project of making past women visible. Rock carvings, which are relatively common over many parts of Europe and cover a time span from the Early Stone Age to the Early Iron Age, were a special challenge, as they highlighted the problem of identifying sex as well as gender when confronted with foreign picture conventions. It has been claimed that all the humans depicted, for example, on Scandinavian rock carvings were male. Gender researchers have challenged such viewpoints and presented convincing arguments that women, women's activities, and in some cases even different (ethnic) gender ideologies are represented on European rock art panels (Figs. 1 and 2).

Graves and Funerary Assemblies

Funerary assemblies will often be associated with individuals and have for that reason been central in gender studies, which have often focused on hierarchical statuses, power relations, and social roles.

Jewelry and weapons have been generally accepted as tentative gender markers. An example of a study based mainly on jewelry is Ursula Koch's (1997) study of two Merovingian cemeteries in Germany. Intimate knowledge of the archaeological material enabled her to divide the burials into families (households) and analyze the female burials in order to reveal geographical origins, ethnicity, and relative ranks of the women in each household. Skeletons were examined in order to determine age and other aspects such as whether the women had given birth. Koch's study does not aim to fundamentally challenge existing conceptions of early medieval women. But through meticulous analyses of finds and contexts, one of the hallmarks of German archaeology, new insights in women's gendered lives are generated and our understanding widened.

Studying roles and statuses from burial finds is most fruitful where burials are individual and gendered differences are indicated in terms of monuments, in body treatment, or in grave gifts. One should note, however, that dichotomous gender roles and other easily recognizable variations will be overrepresented in studies based on supposedly exclusive gender-related artifacts. Another source of error is that often a considerable percentage of burials in the cemeteries investigated cannot be gendered through the grave gifts. They therefore tend to be left out of the interpretations, thereby possibly creating sharper gender divisions than warranted. Finally, a question related to all representations of women (and men) in the past is whether the representations are idealized or realistic ones, gender ideologies or "gender in action."

Subsistence, Trade, and Technology

In spite of the great number of prehistoric settlements known in Europe, these have played a relatively small role in gender studies. One reason may be that tools found in settlement contexts can rarely be definitely attributed to any gender. Interpretations tend to rely on ethnographic and historic evidence, inviting the interpretation of subsistence activities like hunting or farming as men's work. But there also seems to be a general agreement that both women and men must have participated in economic activities in all kinds of societies. Grave gifts sometimes indicate what kind of work the people buried engaged in. As an example, agricultural implements in female graves may indicate that women have taken active parts in farm work during the Scandinavian Iron Age, and scale-weights found in graves indicate that Viking women in Russia may also have been traders, probably participants in family businesses (Stalsberg 1987). More generally, women seem to have been engaged in textile work all over Europe. Again, this is supported both by

grave gifts and iconography (spindle whorls, weaving equipment, and depictions of women weaving).

Technology is a masculine laden word, effectively often leaving women out of fields such as metalwork or boat building, although the question of women's participation has been raised (e.g., Sørensen 1996). A fruitful approach is to point to the fact that activities traditionally considered female, such as ceramic production, textile work, the preparation of food, and caring for people, require skill and knowledge and therefore represent sophisticated technologies. This is the strategy of the Spanish "maintenance archaeologists" (Goncáles-Marcén et al. 2008; ▶ "Gender, Feminist, and Queer Archaeologies: A Spanish Perspective" in this encyclopedia) who claim that these and related activities are basic for the structure and continuation of societies.

Theoretical Approaches/Current Debates

Insofar as the theories are applicable to archaeology, European gender archaeologies have followed the development of second (and third)-wave feminisms. Two issues, however, may be said to characterize the European archaeological scene. One is a sometimes explicit discussion of the relationship between feminist and gender research; second is the conflation of postmodern deconstruction and gender analyses as keys to understanding genders of the past.

Feminist studies are defined by their approach. A feminist study in archaeology may have as its subject any aspect of the archaeological past, men, women, the emergence of agriculture, technological innovations, or religious ideologies. The ensuing new interpretations would not only include women but be made from women's standpoints. Although feminist theories have been fundamental to the critiquing of androcentric science and vital to the early development of gender scholarship in Europe, feminism has not remained a preferred framework of interpretation for all gender archaeologists. Some scholars consider feminism to be political, or biased, while true scholarship should be objective and unbiased. Others claim that objectivity is impossible in humanistic scholarship and that the solution is to recognize your bias and take it into account in interpretations, as recommended by standpoint feminists.

The study of gender (or women), on the other hand, is defined by its subject and may take at least two different directions. One is the anthropologically inspired study of how gender works, that is, how people of the past have lived their lives as women, men, and possible other genders within different cultural contexts. Another approach, which will be discussed in the following paragraphs, is closely linked to the impact of postmodern skepticism and deconstruction in parts of European archaeology and concentrates on the character of gender and gender as an analytical concept.

British archaeologists signaled the analysis of gender as a central concern as early as 1988 (Arnold et al. 1988: 2). Discussion concerning the relationship between gender and material culture as archaeology's special contribution to gender research (cf. Sørensen 2000) is a further development of this theme, postmodern deconstruction and analysis another.

An early comment on the relationship between postmodernism and the study of gender in archaeology relates to the danger inherent in approaches that advocate pluralism and open-ended interpretations, namely, that with no fixed authority to appeal to, interpretation becomes a matter of power (Engelstad 1991). Power is still predominantly male in academic circles, and Engelstad's comment thus reflects the basic idea of feminist scholarship, namely, critique of androcentrism in any form. Another comment would be that by deconstructing the concept of gender, gender studies no longer have an object, and consequently the legitimacy of the field as such is undermined.

In a relatively recent paper, Whitehouse (2007) claims that European gender archaeology as a whole has developed in a post-processual and even postmodern direction, with the consequence that European gender archaeologists tend to neglect the fact that most people worldwide do in fact live and identify themselves as women and men. Central issues like male/female power relations and the role that reproduction and

motherhood must have played in women's lives are likewise excluded. In sum, claims Whitehouse (2007), European gender archaeology has removed itself from the lives of real women and men of the past.

This is a legitimate critique of strands of gender archaeology that seem to have problems accepting the category of "gender" at all. But it is a mistake to assume that this attitude characterizes European gender archaeology. Whitehouse's discussion is based almost exclusively on Anglophone gender archaeology. The trends she criticizes represent one particular European tradition which, because English is the academic lingua franca, tends to dominate the international field. European gender archaeologies are, however, situated within national archaeological communities of scholars. Spanish, German-language, British, Scandinavian, and the emerging East/Central European gender archaeologies all carry the hallmarks of their own local academic traditions, which may be culture historical, processual, post-processual, or postmodern, and favor different issues, approaches, and forms. In many European languages, it is also the case that biological sex and gender are intrinsically linked – even covered by the same term. Native speakers of such languages think differently about gender, thus contributing to the multivocality that is a precondition for new insights.

With these reservations, it is probably still the case that the analysis of gender in all its variations has become one of the most important – in terms of papers presented maybe *the* most important – strands of archaeological gender research in Europe today. Most British gender archaeology today falls into the category of gender analysis. The approach is represented in Scandinavian and Spanish archaeologies as well, although feminist archaeology is also relatively strong in these regions. In German-language archaeology, some scholars prefer working within a feminist framework, while others have emphasized the importance of finding a place for "nonideological" gender research (Mertens and Koch 2005), as, for example, gender analysis.

International Perspectives

Viewed from a Norwegian perspective, the first years of gender archaeology were characterized by a high degree of Scandinavian cooperation and enthusiasm. With the advent of the first English-language publications in the 1980s, a feeling of sharing a common frame of reference and working toward a common goal developed. On a European level, the British TAG conferences became an international meeting place for gender archaeological discussions.

From then on, gender archaeology was definitely an international phenomenon, with steadily increasing communication across borders. The number of publications increased dramatically, especially English-language books and papers. A positive effect was that scholars who wanted to participate on the international arena were often encouraged to publish in English, thus reaching a wider (academic) public. On the negative side is the fact that those who chose to write in their native languages, and thereby also to communicate with the general public in their countries, became more marginalized than ever internationally. The end result of the ongoing internationalization may be that in many European countries, gender archaeology is only occasionally disseminated to local publics.

International communication did not stop at the European borders. Conferences in Europe, North America, and Australia attracted participants from many continents, and the conference papers were read by everyone with an interest in gender and archaeology. Some sources of inspiration were shared by almost all gender researchers. Foremost among these are the writings by feminist theorists like Simone de Beauvoir from France and American standpoint feminists like Nancy Hartsock and Sandra Harding, who became household names to anyone working with women and gender. Donna Haraway and Judith Butler have also influenced European gender archaeology considerably, as have the philosopher/archaeologist Alison Wylie and gender archaeological pioneers like Margaret Conkey and Janet Spector.

International contacts tend to be unilateral between Britain (or the USA), where well-known international centers of education are to be found, and individuals of other nationalities. In the context of gender archaeology, however, multilateral contacts within Europe should not be underestimated. Naturally, these tend to go between regions with related traditions in culture and language, as reflected in the regions discussed above, but wider networks have also been established. From 2008 onward, European gender archaeologists have had a common meeting place in the working group "Archaeology and Gender in Europe" (http://www.upf.edu/materials/fhuma/age/), part of the European Association of Archaeologists (EAA). One of the goals of this network is to ensure that information and inspiration will cross borders and oceans in all directions.

Future Directions

In archaeology, gender research has been mainly an academic field or a discourse between archaeologists. But archaeology also has a role to play in society at large. Doing gender archaeology should, among other things, mean reaching out to the general public and presenting recent research through popular books and papers, museums, and other media.

Gender Studies and the Archaeological Record

The archaeological record, or the material remains recognized mainly through surveys and excavations, kept in the landscape or stored in museum collections, is the basis of all archaeological interpretations. Today, most of the additions to the archaeological record are results of rescue excavations taken on not for academic reasons but because the land in question is being developed for new purposes.

Increasingly, rescue archaeology is carried out by commercial firms, although guided by local heritage legislation and international agreements. In Europe, rescue archaeology works closer to the processual paradigm than does academic archaeology. The general opinion seems to be that (gender) theory is not relevant to rescue excavations or to the excavation phase at all: interpretation comes later. Large-scale excavations also tend to be headed by men, something that has not favored gender or feminist approaches. In the future, a closer relationship between rescue archaeology and academic research would be desirable in order to generate gender-relevant discoveries in creating the archaeological record and activating its potential in research and dissemination.

Gender in Teaching, in Museums, and in Books Directed at the General Public

Gender archaeology has a long history in teaching departments, and many universities offer courses in gender archaeology at different levels. Dissertations in gender archaeology have also been defended all over Europe from 1976 onward, in sum an imposing body of new knowledge.

The dissemination of all this newly generated knowledge to the general public, however, seems to be lagging behind. Museum archaeologists have been involved in gender archaeology from early on, but in spite of this, there have been far too few permanent museum exhibitions incorporating gender-relevant questions or women. Occasionally smaller, temporary exhibitions dedicated to women in the past are shown. A future task would be to include a gender aspect in all museum exhibitions, especially the permanent ones.

Another arena not yet conquered is that of general historical accounts, in textbooks and overviews aimed at nonspecialists. Like museum exhibitions, these tend to be conservative, and gender is seldom in focus. Incorporating the results of gender archaeology into the great narratives of humankind has been the main motivation of gender archaeology from the 1970s onward. It is now time to make this a priority in future work.

Gender, Feminist, and Queer Archaeologies: USA Perspective

Benjamin Alberti[1] and
Ing-Marie Back Danielsson[2]
[1]Department of Sociology, Framingham State University, Framingham, MA, USA
[2]Department of Archaeology and Classical Studies, Stockholm University, Stockholm, Sweden

Introduction

This entry presents a brief history of the emergence of feminism, gender, and queer in North American archaeology, which, along with the United Kingdom and Scandinavia to a lesser degree, represents the geographic origin and center of such work. The key concepts as used by archaeologists are defined; the relationship among them is explored and shown to be both problematic and productive. The place of feminism,

gender, and queer within North American archaeology today is characterized and, finally, likely avenues of future research are suggested. The greatest impact of feminist, gender, and queer archaeologies has been on the authority of positivist approaches, the objectivity of interpretation, equity issues within the profession, collaborative knowledge making, and the understanding of key archaeological interpretive concepts.

Definition

None of the terms "feminism," "gender," or "queer" have fixed meanings. Different academic disciplines have their own interpretations, histories, and methods embedded in each. In the following, the terms are defined in relation to how they have been used and employed within archaeology. Contrasts are drawn between North American and other usages, where relevant. Feminist archaeologies emerged in North America in the early 1980s; queer archaeologies were inaugurated in the early 2000s in both North America and Europe. Gender as an explicit object of study emerged with feminism. Stereotypically, feminist and queer archaeologies have been assigned their proper objects of study, mimicking that same division of labor in academia more broadly: feminism studies gender, while queer approaches are centrally concerned with sexuality. In actuality, neither feminism nor queer in archaeology need be limited to these objects of study.

Feminism

Feminism is recognized as an approach rooted in contemporary political goals. Feminist social science commitments are those that are relevant to women and others oppressed by gender structures (Wylie 2007: 211). Feminism in archaeology is concerned with the conditions of archaeological knowledge production in the present and the reconstruction of the past and past peoples' lives. Since this concerns power relations, focus is often – but certainly not exclusively – on women (Tomášková 2011). Feminism in archaeology is further about recognizing gender bias, rewriting histories of the discipline and the past that exclude or downplay the role of women, questioning the alleged neutrality of science, and addressing equity issues in the discipline and the theoretical development of key concepts, especially gender, but also power, bodies, and the State, among others (Conkey and Spector 1984; Wylie 2007). Ultimately, feminist archaeology involves a fundamental rethinking of the questions archaeologists address and the frameworks they use (Conkey 2005; Wylie 2007).

The feminist critique of science has come to dominate North American feminist archaeology and can be seen to constitute the orthodox approach. Work typically draws on feminist philosophers of science, such as Helen Longino and Sandra Harding (Wylie 1992, 2007). This orthodoxy co-exists with a lesser post-structuralist feminist production inspired largely by the work of feminist philosopher Judith Butler (e.g., Joyce 2008), which is concerned with questions of discourse and the performance of gender. Butler is a useful figure who crosses the divide between continental post-structuralist feminists and social science feminists by using a vocabulary of gender and performance. Work that draws on Butler in gender archaeology shares the concern of the feminist critique of science with empirical adequacy and evidential constraints (Joyce 2008). The more radical elements of Butler's and other continental feminist philosophers' work tend to be re-categorized as queer. Regardless of the type of feminism, all share a set of concerns around *reflexivity*, *accountability*, and *reframing* key debates.

Reflexivity

Reflexivity has its roots in feminism's grounding in the experience of oppression of women, where people are understood as constituted by their experiences rather than simply "having" them (Conkey 2005: 27). Reflexivity also refers to a commitment "to locating the researcher on the same critical plane as the researched" (Marshall et al. 2009: 226). The importance of reflecting on daily lives is double: research is founded on the experience of the everyday life of women and marginalized people in the present and aims to validate the lived experiences of past peoples, to

"people the past" (Spector 1993; Joyce 2008). A reflexive, situated archaeology is a response to the insight that all research reflects the position of the researcher within a given social structure and incorporates the pragmatic interests of that position. Counterintuitively, this is seen as the central virtue of reflexivity. A situated, feminist archaeology raises the bar epistemologically because it is a "critical, theoretically informed, *standpoint* on knowledge production" (Wylie 2007: 213).

Accountability

Accountability to research subjects is of central concern. The situatedness of knowledge production means that issues of power are recognized as inherent to all aspects of the research process. Archaeology is recognized to be inescapably political, as is the knowledge it engenders. A concern with ethical and pragmatic norms means that egalitarian and collaborative forms of knowledge production are sought, leading to community archaeology projects and alternative writing genres (Spector 1993; Joyce and Tringham 2007; Marshall et al. 2009). Accountability also refers to the recognition that feminist research is simultaneously about the past and how versions of the past are sustained or not (Conkey 2005: 33).

A widespread acknowledgment among feminist archaeologists is that while feminist research starts with the experience of women, it should ultimately lead to a general *reframing* of questions, practices, theories, and goals within the field as a whole (Conkey 2005: 26; Wylie 2007). In this regard, feminists question the central concepts of archaeology, such as technology, inequality, household, hunting/gathering, gender, and bodies, as well as archaeological practice and theory (Wylie 2007).

Gender

The original formulation of gender in archaeology was adopted from a social science understanding in which sex referred to biology (male and female), and gender referred to the meanings ascribed to that biological foundation by particular cultures. As such, gender is commonly understood as a social or cultural "construction." Conkey and Spector's (1984: 16) groundbreaking article "Archaeology and the Study of Gender" defined gender as "a system of social rather than biological classification that varies cross-culturally and changes over time" and stipulated a range of ways in which gender could be conceptualized and studied, including roles, identity, and ideology. Gender attribution was a central concern. Genders could be identified archaeologically through burials, representations, tool use, and skeletal remains by associating cultural items with biological sex or its representation. Ethnoarchaeology was also seen as key to illuminating the range of activities in which males and females were engaged.

Gender is now recognized as a historical process and a major structuring principle of societies of the past and present (Gero and Conkey 1991). Gender is also increasingly thought of as more a process than a static ascription of identity or one among a list of social variables. It can also be thought of as an ongoing embodied and performative process of identity formation which structures relations. Thus, gender is also relational (Joyce 2008).

Gender implies a definition of sex. The conceptual foundation of gender is the ascription of cultural meanings onto male and female bodies; even when gender is understood to be an important element of how societies, in general, are organized, this foundation remains. This means that when gender is explored as a social variable, even a structuring one, it is used to provide interpretations of historically and culturally specific ways of organizing people on the basis of difference grounded in binary sex. The concept itself is rarely open to theoretical reconsideration within the social construction formulation.

The concept of gender initially served the important purpose of liberating interpretation from the essentialism of sex role identity, where one's sex was assumed to determine one's capacities and roles in society (Conkey and Spector 1984). Quite quickly, sex was questioned as a static foundation for culture to ascribe gendered meanings – sex was also recognized as historical (see Joyce 2008). The

implications of the critique of sex have resulted in work on embodiment and performativity (Joyce 2008). Arguably, not even these approaches manage to dispense with the distinction between sex and gender which rests on that between nature and culture, although the nature of the relationship has been rethought.

Finally, some archaeologists, especially those influenced by queer theory, question the unconditional relevance of gender in all contexts (Joyce 2008), while others continue to argue that its central importance to feminist archaeology should be given (Wylie 2007).

Queer

Queer refers to a deliberate strategy by activists and academics to reclaim and redefine a word in terms of identities and bodies that avoid the essentialism of more conventional forms of identity labeling. In North American archaeology, queer theory has predominantly inspired work on sexualities (Schmidt and Voss 2000; Casella and Voss 2011). Nonetheless, queer also implies a critique of the ubiquity of heteronormativity, the notion that an assumption of heterosexuality underlies many political and social structures (Dowson 2006; Voss 2009).

Queer archaeology, in general, includes redemptive counter-histories that bring to light previously hidden histories of sexualities (Voss 2009), queer statements that challenge heteronormativity beyond a focus on sexuality (Dowson 2000), and work on embodiment predominantly influenced by Judith Butler's theory of gender performativity (Joyce 2008). Thus, the naturalization of heterosexual institutions such as the family and the division of labor is challenged (Dowson 2006; Voss 2009). Past identities are understood to be constructed in fluid ways (Joyce 2008). In common with feminism, queer critiques have appeared in response to equity issues within the discipline, such as the relationship between non-straight subjectivity and professional success and the "epistemological privilege" of straight archaeologists and their accounts of the past, although this trend is more visible outside North America (Dowson 2006; Voss 2009).

Historical Background

Gero and Conkey (1991) inaugurated a reflexive, self-conscious history of feminist archaeology in which the "three fold" development of feminism in the social sciences is cited: the critique of androcentrism and destabilizing assumptions about women's capacities, the "remedial" search for women in the past, and finally the theoretical development of gender as a concept. As such, feminism and gender co-emerged in archaeology.

Prior to the early 1980s feminist work had little visibility and much was outside the English-speaking world. Conkey and Spector's (1984) article is a milestone in feminist and gender archaeology; in it, the authors presented the case for the general applicability of gender and feminism. They presented a critique of androcentrism in the discipline, argued that in the absence of an explicit framework for theorizing gender archaeologists drew on common sense understandings, and provided a set of conceptual tools with which to address gender in a systematic way.

In the late 1980s, two quite different but equally agenda-setting events occurred: the small conference at the Wedge Plantation in 1988 and the far larger, student-organized 22nd Chacmool Calgary conference in 1989. Frustration with the slow development of gender archaeology led to the Wedge conference where the goals of the 1984 article were deliberately pursued in a series of detailed case studies (Gero and Conkey 1991). The Chacmool conference was notable for the number of papers presented as well as debate around the question of the relationship between gender and feminism.

Recently, the stance that gender archaeology in North America is feminist within the terms of the feminist critique of science was reaffirmed in a 2007 special issue of the *Journal of Archaeological Method and Theory* (although based on an earlier conference) (Wylie 2007). Particular emphasis was placed on feminist praxis. In her introductory paper, Wylie (2007) reorients the question away from "feminist archaeology" and toward what it means to do work as a feminist archaeologist. Epistemological issues remain at the forefront, including questions about the

gender of theory and the intersections that are possible among marginalized perspectives within archaeology (see also Conkey 2005). Since Janet Spector's (1993) groundbreaking book, *What This Awl Means: Feminist Archaeology at a Wahpeton Dakota Village*, feminist concerns have been increasingly seen as paralleling those of class, race, and indigeneity, resulting in collaborative projects and de-centered authorship. In addition, issues of representation have led to alternative writing genres, explorations of language, and research in hyper-media as a means of representation (Spector 1993; Joyce and Tringham 2007). North American leadership in the field of gender archaeology was demonstrated by the publication of the *Handbook of Gender in Archaeology* (Nelson 2006), which provided an exhaustive survey of the field from thematic, temporal, and geographic perspectives.

Feminist archaeology has rarely influenced feminist debate beyond archaeology except in the form of review pieces in general interdisciplinary surveys of feminism, of which there have been few. An exception is Marshall's (2008) contribution in the journal *Feminist Theory*, which prompts feminists to explore change, transition, and transformation using the archaeology of the Pacific Northwest as a case study.

Queer archaeology in North America has its roots both in feminism and the study of sexualities, first gaining visibility through two edited volumes published in 2000 (Dowson 2000; Schmidt and Voss 2000). Queer work in North American archaeology is generally influenced by Judith Butler and work on sexualities, resulting in specific case studies on bodies and performance or explorations of sexual identities, most often in historical contexts. It is recognized that many of queer archaeologies' concerns parallel those of feminism, where its roots lie (Voss 2009).

Queer is not overly visible in North American archaeology today. In an attempt to galvanize a focus on queer and gender archaeology, the 2004 Chacmool conference was organized around the theme "Que(e)rying archaeology"; even though it produced statements from leaders in the field surprisingly few queer papers were presented. Recent work on sexualities and colonialism may indicate a new avenue for queer research in archaeology (Casella and Voss 2011).

Key Issues/Current Debates

Some long-standing and some recent debates cross-cut feminist, gender, and queer interests, while others feature more strongly in one area. The key issues outlined here are (1) the relationship between feminism and gender; (2) epistemological concerns; (3) accountability; and (4) identities and embodiment. In the latter, the question of whether gender is necessarily relevant to all identities is raised.

The Relationship of Feminism to Gender

The question of whether gender archaeology need necessarily be feminist emerged in the late 1980s and has not entirely gone away. Gender is now present in many conventional archaeological interpretations alongside other social variables, but feminism is rarely mentioned. This is seen as a problem for some feminists who argue that gender without feminism loses the possibility of producing fundamental change (Conkey 2005; Wylie 2007). Moreover, feminist theoretical resources enable gender to remain as a dynamic concept in archaeology and allow us to account for the "epistemic and political commitments that inform practice" (Wylie 2007: 215).

The counterclaim is that feminism introduces an unnecessary political bias and risks further isolating gender from the mainstream. Though, it has been claimed that feminist epistemological concerns are central to gender work in archaeology at all levels irrespective of whether the label is used (Tomášková 2011).

Most feminist archaeologists retain the concept of gender in their work; gender as a category of analysis is still needed, even if expanded in scope (Conkey 2005: 19). Wylie (2007: 213) argues for the methodological axiom that gender should not be disappeared. Queer and some feminist archaeologists, however, see gender as a potential barrier to conceptualizing identities and bodies in non-binary ways (Joyce 2008). Many continental feminists, for example, do not work with the notion of

gender at all, but rather work through sexual difference. Judith Butler is a bridging figure who draws on sexual difference feminists but uses the social science conceptual language of gender, which may account both for her popularity and the misunderstanding or disavowal of some of the more radical implications of her work.

Epistemology

The charge leveled against feminists that objectivity cannot be maintained when an explicitly politically oriented approach is taken is rebuked by feminist archaeologists who claim that feminism can provide better, more objective accounts of the past while simultaneously valuing ambiguity (Conkey 2005). Thus, in common with post-processualism, feminist archaeologists tend to be concerned with the nature of political influence. Though, feminism is even more concerned with equity issues, leading to some adversarial exchanges on the grounds that post-processualism simply reproduces androcentric and heterosexist structures in the discipline (Tomášková 2011: 113–115).

Conkey and Spector (1984: 21) argued that the greatest limitations on our knowledge of the past are epistemological rather than lack of data (see also Wylie 1992). Epistemological concerns have to do with what we say about the past, how we go about saying it in a reasonable and justifiable way, and who has the authority to speak – all parts of the feminist method debate (Wylie 2007: 211). Questions that have concerned North American feminist archaeologists in relation to archaeological practice include ending inequality in the workplace, methodological issues, especially around objectivity, and who has the authority to speak. Workplace inequities are real and systematic, and the politics of gender affects data collection and interpretation in profound ways (see contributors to Gero and Conkey 1991).

The method debate is commonly phrased in terms of how to have gender while keeping archaeology objective, neutral, value-free, and scientific. Feminist archaeology has established itself as a legitimate field partly by addressing conventional archaeological concerns about empirical adequacy, hence its long-term protagonism with processual archaeology. One response has been the argument that gender archaeology can lead to "processual plus," a better but fundamentally unchanged processual archaeology (see Tomášková 2011: 115). The suggested has been criticized as an add-on to an unreflexive positivist approach (Tomášková 2011). In contrast, by locating feminist archaeology firmly within the tradition of post-positivist feminist critiques of the sciences, a philosophical space is opened for an engaged feminism without conceding the legitimating authority of science. Feminist archaeologists argue that it is the reflexive recognition of our standpoint as positioned subjects that provides the grounds for "strong objectivity" (Wylie 2007: 213). Wylie (1992: 30) has argued that "politically engaged science is often much more rigorous, self-critical, and responsive to the facts than allegedly neutral science, for which nothing much is at stake." Accordingly, social location rather than a polluting effect of our subjectivity is constitutive of the research process and simultaneously decenters a singular, authoritative science and hence opens the way to legitimizing other perspectives.

Ambiguity of data and interpretation is embraced by some feminist and queer archaeologists; data are irreducibly ambiguous, so interpretations must be uncertain and open (Conkey 2005: 25). To think otherwise is to falsely reduce complexity, to seek closure and causal simplicity (Wylie 2007: 213). Feminist archaeology adopts "strategic ambivalence" (Wylie 2007: 81) that refuses both unreflective objectivism and reductive constructivism. Empirical constraints exist but feminist archaeology has created an alternative epistemic position that also recognizes ambiguity and sociopolitical factors (Conkey 2005).

In queer theory, the impact of subjectivity on what pasts get written meets feminist critique in the recognition that masculine norms define the process of professional socialization, with institutions reproducing gendered and sexually normative conventions (Wylie 2007; Voss 2009).

Accountability

Feminist archaeology is concerned with ethical and political responsibility for knowledge

production. Recognizing the stakeholders in knowledge claims implies a different type of research practice involving the formulation of questions, the control and management of projects, and the forms of knowledge dissemination. Spector's (1993) work has achieved iconic status. Her project included Wahpeton Dakota people from the outset; she then wrote an account that melded conventional scientific analysis and presentation of the data with reflexive discussion of the research process and narrative reconstructions of the life of a young Dakota girl.

The question of accountability can also refer to the early and ongoing effort to recover women researchers whose contributions to the history of archaeology had been lost. Similarly, queer archaeologists, while signaling the danger of writing a history of deviants, stress the importance of uncovering a queer heritage to counter sometimes brutal contemporary politics (Voss 2009).

Joyce and Tringham (2007) stress the multiplicity of voices that need to be recovered from the past. Other authors have experimented with nonconventional narrative reconstructions of archaeological data (Spector 1993) in an attempt to get away from exclusionary scientific discourse. The BACH (Berkeley Archaeologists at Çatalhöyük) project's "Remixing Çatalhöyük" website (http://okapi.dreamhosters.com/remixing/mainpage.html), in which knowledge of the Neolithic site is created and mediated through an experiment in multi-vocal "open construction," clearly draws on Ruth Tringham's earlier, explicitly feminist work (Joyce and Tringham 2007). The inclusion of a broad range of publics in archaeological debate and interpretation of the past has resulted in the development of other web-based projects, such as the "Sister Stories" hypertext work, which presents fictional accounts based on Nahuatl-language texts about the Aztec capital, Tenochtitlan (Joyce and Tringham 2007).

Identities and Embodiment

Initially, the notion of gender identity was used in a straightforward way as the compliment to a socially constructed idea of gender (Conkey and Spector 1984). While it is still used commonly in this form, the introduction of post-structuralist feminist and queer theory that challenges the notion of a stable core to identity has led to work that conceptualizes identity in nonessentialist ways. Work on the archaeology of the Chumash of coastal southern California shows that identities may only be relationally relevant, based more on practice and profession than an enduring attachment to biologically based categories (see summary of Sandra Hollimon's work in Joyce 2008). The case demonstrates that we need not assume that identities are stable or co-terminus with bodies or that age and gender categories remain universally recognized and fixed.

The limited work on masculinities in archaeology provides an interesting case of the limits of identity archaeology (Alberti 2006). In archaeology, successful accounts of historically and culturally specific masculinities have demonstrated that identities associated with male bodies are highly variable and hierarchically organized (captured by the model of "hegemonic masculinities"). Most work in this genre has been carried out on documented cases. A notable recent example is the archaeology of the University of California's chapter of the Zeta Psi fraternity (Wilkie 2010). Wilkie (2010) uses a rich array of archaeological, architectural, and documentary evidence to reconstruct the changing and heterogeneous nature of modern masculinity from the late nineteenth to mid-twentieth centuries. However, the use of the term "masculinity" outside of historical contexts may have the paradoxical effect of reinstating an ahistorical essentialism to masculinity (Alberti 2006).

The concept "embodiment" was developed to explore ways in which identity and bodies can be thought of in nonbinary ways (see Joyce 2008). This perspective accompanies a critique of the sex/gender dualism as a timeless structure. Sex is understood to be equally historically contingent; a critique that has actually been present since early in the history of gender archaeology. One result has been the development of archaeologies of embodiment and the theory of gender performativity (Joyce 2008). Embodiment indicates that all people experience their worlds from specifically embodied perspectives and, moreover, that a gap can exist between an individual's

or group's embodied experience and the norms or expectations of the dominant society. Not all people or groups experience their bodies and society's norms the same way; such norms have a differential and sometimes exclusionary impact.

Judith Butler's theory of gender performativity has been a major influence on the archaeology of embodiment. The theory has been taken in archaeology to mean that gender is a kind of incessant action involving dress, gestures, and material culture, in fluid relationship to the materiality of the physical body (Joyce 2008). Such acts enforce or naturalize sex into historically contingent organizations, stereotypically binary in the modern West.

International Perspectives

Norway, along with Sweden, saw the establishment of a feminist archaeology in the late 1970s and 1980s; the United Kingdom was also an early influence. Today, however, North American archaeological publications devoted to issues concerning feminisms, gender, and queer dominate (Fig. 1). As such, they serve as a source of inspiration for feminist archaeology in Scandinavia, although the interest does not appear to be reciprocated.

Gender, Feminist, and Queer Archaeologies: USA Perspective, Fig. 1 Number of gender research articles published in archaeology by country between 2001 and 2010 according to Thomson & Reuter's Web of Science (Arts & Humanities Citation Index, ISI). Gender research includes keywords, such as gender, feminism, masculinity, queer, embodiment, and intersectionality. There were 97 gender articles published out of a total of 3,525 archaeological articles

There are apparent differences in the scholarship on queer archaeology between North America and the United Kingdom. North American work tends more toward studies of sexuality, bodies, and performance (Schmidt and Voss 2000; Joyce 2008), whereas queer theorists in the United Kingdom and Scandinavia often take the dictum that queer is about opposition to the norm as their starting point (see contributors to Dowson 2000). Moreover, the genealogical relationship to feminism is stressed less in the United Kingdom. Exclusions in feminist scholarship have been noted, such as the assumption of normative family structures or the implication that sexuality is a secondary effect of gender (Dowson 2006); and epistemological concerns in relation to queer are more visible. Marginalization of studies of sexuality in archaeology and the recognition that the past is always already heterosexual has been linked to the question of epistemological privilege – whose account of the past is given greater credibility (Dowson 2006).

Future Directions

Work that takes gender as a social variable seems entrenched in North American archaeology. The most exciting theoretical developments, however, are in feminism and queer archaeology, including work on intersectionality, community or public archaeology, and new feminist and queer materialisms.

It has been argued that intersectionality and the postcolonial critique represent a turning point for archaeology in general (Conkey 2005: 10). Intersectionality is a means of describing and theorizing the many intersections among gender and other elements of identity, such as "race," class, age, and sexuality, within complex sociopolitical contexts. It is clear that an analysis of gender alone is inadequate – gender is constituted by its intersections. Earlier convergences between the interests of feminists and indigenous peoples in North American archaeology (e.g., Spector 1993)

have been reframed and explicitly theorized as intersectionality (Conkey 2005). Within this framework it is understood that multiple relations of domination result in privilege, differing positions and hierarchies among communities and individuals. In this light, Conkey (2005: 12) redefines gender as a contingent set of ideas and practices within multiple systems of oppression. The type of analysis entailed directs us toward the small scale, to daily lives, and the specific details of singular sets of relations. One point of intersection is the need to understand how inequality, in general, works in our present-day lives and in the lives of past peoples. However, just as intersections are needed precisely because of the partiality of perspectives, as feminist epistemology has outlined so clearly, Conkey (2005: 25) warns against scaling down or making hierarchical the relations that are intersecting, reducing, or subordinating one relation to another. Seeking clarity about gender, ironically, could produce just such a privilege.

Work in this genre includes contributions to Casella and Voss (2011), which demonstrate the constitutive intersections of sexualities, embodiments, and colonialism. Battle-Baptiste (2011) presents a non-formulaic Black feminist reflexive methodology to study the intersections of "race," gender, and class in the historical archaeology and history of Diasporic African Americans. There are also strong connections among intersectional approaches and recent Marxist archaeologies of praxis.

Although located in the United Kingdom, one model for the important convergence of feminist and queer approaches is the archaeology of the women's protest camps at Greenham Common (Marshall et al. 2009). The camps were occupied by women and children in the 1980s to protest the deployment of Cruise missiles. Spector's (1993) work, which emerged from a concern that archaeological practices and interpretation be meaningful on human terms, is a clear antecedent. In the Greenham Common case, the reflexive autoethnographic narratives of the three women researchers provide a possible model for feminist and queer archaeology, where issues of authority, vocality, and intersectionality are put into practice. Refusing to stay outside of Greenham's politics (Marshall et al. 2009: 233), their research method mirrors the queer nature of the site, with women and children living outdoors in communities and adopting practices that were threatening to heteronormative society.

On more speculative theoretical grounds, one direction that diverges from current work in North American archaeology but has its roots in queer and feminist approaches is a renewed interest in materiality. In the social sciences, in general, there is much recent interest in "post-human" approaches to materiality and identity. This is partly a response to what are thought to have been the excesses of the linguistic turn, represented in archaeology by symbolic and interpretive approaches under the umbrella of post-processualism. The theory of gender performativity, for example, would appear to give culture or discourse too much power over bodies and materiality. Archaeologists are consequently returning to the materiality of their subject matter as a source of agency in social life. In relation to sex and gender, this can take the form of a reassessment of the agency of the body conceived of as plastic and developmental rather than static. Or the body's natural variability and peoples' experiences of their embodied selves can be thought of as never fully erased by discourse and therefore free to challenge the binary gender/sex model (Joyce 2008). New queer and feminist approaches to osteoarchaeology in North America stress that knowledge of the sexed body is historically bound and thus open to future reformulations (Joyce 2008).

Tomášková (2011: 113) has recently asked whether gender archaeology is thriving. While gender in archaeology clearly has an enduring legacy and the impact of feminism on the discipline is undeniable, they arguably have not produced the sought after revolution in archaeological questions, frameworks, and practice. Has gender archaeology lost its cutting edge, its aura of creativity? One legacy of feminist archaeology is the space opened up for queer archaeology

(Dowson 2006; Voss 2009). In some ways, queer has come to occupy the position of the radical side to gender archaeology and has taken on elements of a feminist project not addressed by more orthodox feminist approaches in the discipline.

Genealogy on the Web: Benefits and Limitations

Doreen B. Kosak
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Probable conclusions about the ways people lived in the past can be made by archaeologists, genealogists, and family historians by using the same or similar resources for their research. Before the arrival of the Internet, researchers from these disciplines visited archives, libraries, and other repositories to view historical records, and their means of communication was by letter or telephone. Today's researchers can use the Internet which has provided a platform for resources to be shared in what is often called the world's largest library (Paton 2011: 1) – the World Wide Web (the Web). The Web has revolutionized the way people research, learn, and communicate both commercially and socially. It has benefits for archaeologists, genealogists, and family historians because of the opportunities to extend their research internationally and communicate with others easily. While the Web has many advantages for genealogical researchers, it also has some limitations.

A genealogical family tree whether digital or on paper is a database of personal information about individuals connected to one another by lines of family descent. It gives the names, dates, and events such as a birth, marriage, or death and the places that these occurred. As their research progresses, genealogists and family historians broaden their investigation to include the occupations, military service, and other social history that involve their ancestors and extended family. They can spend many decades researching, collating family trees and histories, and sharing their results with members of their family or the wider community. Archaeologists can find useful information for their research among the records produced for and by genealogists and family historians (▶ "Genealogy, Its Relevance to Archaeology").

Definition

A genealogist researches and traces "the descent of a person or family through an ancestral line" (Macquarie Dictionary 2018). Genealogists may have formal training, or through the experience of researching their own family, they advance to working as a professional genealogist. Family historians may work in a professional capacity but are usually researching their own family's genealogy and history.

The Internet, also known as the "Net," is defined as "the communications system created by the interconnecting networks of computers around the world" (Macquarie Dictionary 2018). The World Wide Web, also known as the "Web," is defined as "a large-scale, networked information system for documents in HTML released to users of the Internet" (Macquarie Dictionary 2018).

Historical Background

In the past, genealogical research was conducted in organizations such as archives, libraries, or church parishes for the records necessary to create a family tree, with additional information being provided by members of the family. Because letters were the main means of communication (Barratt 2010: 19), these, together with other documents, memorabilia, and oral histories were the ways genealogists and family historians learned about their family. However, this meant that a considerable amount of time was involved in correspondence, telephone calls or travel to visit these people and places, often limiting the access of genealogical resources to people who were financially better off or retired (Lynch 2008: 1).

In 1996, online family history research was launched by Ancestry Publishing (Ancestry Corporate 2018), and in 2003 Findmypast was licensed to publish birth, death, and marriage indexes online (Findmypast 2018). Since then, more and more records have been uploaded to the Web and are available to subscribers. The advent of the Internet has now changed the way genealogical and family history research is conducted; it is no longer necessary for people to

visit archival repositories because they can research from the comfort of home, and all that is needed is a computer and access to the Internet. This is beneficial for everyone but especially to the elderly or those with physical impairments who are restricted or confined. Records can be accessed from archives in other cities, counties, states, or countries. There are archival, subscription, organizational, and personal websites that provide genealogical resources, making family history research easier. More information can be gleaned in less time, and cross-checking and communication with archival repositories and other researchers can be more straightforward.

The amount of genealogical research material that is now available online is greater than ever before (Paton 2011: 1). However, this can mislead genealogists and family historians into assuming that finding ancestors on the Web is an easy exercise; it is not, and it may take many years to follow a trail with success (Barratt 2010: 9). Researchers may also believe that because it is in print or online, it is correct, and this is not always the case.

With the advent of the Internet and growth of resources on the Web since the early twenty-first century, genealogy is enjoying renewed interest and media attention. It is a growing industry and produces many useful resources for both genealogists and archaeologists.

Key Issues/Current Debates

Original documents are one of the primary sources of information used by genealogists and family historians; thus archives, other organizations, and private individuals are increasingly digitizing and uploading records onto their websites. While the Internet has made research easier, there are some experienced genealogists who believe that it should not be the primary source of information but used as a starting point and a means to extend their research (Barratt 2010: 9; Hicks 2011: 7).

Sharing over the Internet

Hand-drawn family trees are being replaced by computer-generated trees, and genealogists can share their research over the Internet. This can be done by creating a family tree on a computer database called a GEDCOM file (GEnealogical Data COMmunications) (Barratt 2010: 33–34). The GEDCOM file can be uploaded to a personal website or a subscription website such as Ancestry or Findmypast, and then viewed and downloaded by someone else. It is not necessary to purchase a genealogical computer program because GEDCOM files can also be created on subscription websites and can be viewed and added to during the life of the subscription. If the subscription is not renewed, alterations and additions cannot be made to the family tree, but it is usual for it to remain on the host site. This ease of access to pre-prepared family trees via GEDCOM files can be beneficial to other researchers, but indiscriminate downloading without checking the accuracy of another person's tree can also create problems for genealogists.

Internet Concerns

One concern that is currently debated by the genealogical community is the ease that the Internet provides information to a researcher and its potential for errors. While it has been argued that the Internet is a benefit to genealogical research, one of the questions concerns the attributes of the researcher, for example, does the person have genealogical research skills? Are they following correct genealogical procedures? Are they recording the source of their information? Do they have backup support of experienced genealogists through society or other membership of a genealogical authority? Because researchers can upload their research via a GEDCOM file and share it, if they have made mistakes and incorrect assumptions, these are perpetuated when the files are downloaded by others. The accuracy of another person's GEDCOM file should always be checked before importing it into a database.

Commercial Enterprises and Subscription Websites

Subscription websites such as Findmypast and Ancestry provide original documents to fee-paying subscribers who can search the records and create a family tree, attaching the documents, photographs, and stories to the people

on the tree (Barratt 2010: 90; Paton 2011: 10, 184). Subscription websites may be available for free at public libraries, and genealogy societies usually have a library subscription which is available to their members. These websites vary in their resource content but can include birth, marriage, and death certificates, census records, UK 1939 Register, and military, occupational, and school records (Ancestry 2018; Findmypast 2018). The subscriber can choose to keep their family tree private (Barratt 2010: 33) or make it visible to other subscribers (Paton 2011: 184) who are able to download the tree via a GEDCOM file if they see family connections. This provides an easy-to-use system of building a family database; but, it does come with a few disadvantages such as the limitations of the researchers as previously discussed. However, subscription websites do provide tutorials and newsletters to their subscribers to assist them in the correct procedures of genealogical research, using their sites to best advantage.

Not all genealogists are experienced researchers; thus, the accuracy of their data may be compromised. If documents are attached to the person, then they can be checked, but if they are not, then it is possible that the data may be poorly sourced and referenced. The researcher may have made assumptions about another person's research and attached their tree to their own. All family trees and other archival material attached to them may have transcription or research errors in the recording of information by another genealogist, family historian, or archive. All information should be verified with original documentation where possible or at least a question mark if it is unsure or unknown; otherwise it can result in the importation of a flawed GEDCOM file (Barratt 2010: 37).

In his discussion of resources, Dale Johns (2017), President of the South Australian Genealogy & Heraldry Society Inc., stated:

> The challenge for the researcher is to identify credible, authoritative and reliable sources of information to accurately portray the lives of their subject families and in turn provide valid sources (of) genealogical knowledge.

Genealogy Societies

Genealogy on the Web can create a state of ambivalence for some genealogy societies who have large library holdings and records. Digitization of records is slow, and meticulous care is needed when transcribing from original documents and creating indexes, and local knowledge is useful for this process to minimize errors. While societies are actively scanning their records, indexing, and making them available to their members, they are questioning just how much they should put online. One solution is to make the indexes available to nonmembers with access to the full records on joining the society. The more that societies put online, the easier it is for members to research from home and the less face-to-face contact they will have with the society and the support it provides. A greater online presence could result in fewer people needed for the operation of societies, and thus over time their knowledge and expertise are lost. Frustration does occur in researchers who do not check beforehand but travel to genealogy societies and historical archives to find that records are now only available online at subscription or pay-to-view websites.

Addressing Some Limitations

Unlike academic research there is a limited peer-review process that family historians undergo before publishing their family trees or stories online or in print. Genealogy societies and universities are seeking to address these issues by conducting courses; many of them are online (▶ "Genealogy, Its Relevance to Archaeology"). There are also legal issues regarding publishing information about living people because of identity theft and privacy concerns; therefore, publishing online becomes an issue of invasion of privacy if written permission to publish was not obtained beforehand. Uninformed family historians may be breaching copyright by using photographs or maps lifted from the Web without permission, or they may not be acknowledging their sources. Better support and education will address these issues, but it requires the genealogist or family historian to avail themselves of it by enrolling in

courses or joining a genealogical society; stay at home Web researchers may not do this.

Social Media and Genealogy

In the past, the means of mass communication was by newspaper, radio, or television. Families who wanted to announce a birth, marriage, or death usually did so with an advertisement in the personal pages of their local newspaper. These announcements can still be found by a search of the newspaper concerned. Libraries, other archives, and some genealogy societies keep digital and sometimes physical copies of the newspaper announcements so that it is still possible to search and view advertisements that may be decades old. However, today's society has embraced social media such as Facebook, Twitter, Myspace, and Flickr, and it has now become the place to announce special events: arrivals of new family members, departures of others, and marriages or relationships, together with the associated photographs. Although social media has not replaced newspaper announcements entirely, it has become a quick and easy alternative. The benefit of newspaper personal pages is that they can be scanned or transcribed and a searchable index created for future use. Social media does not have an index, and so it is impossible to look up an announcement without scrolling through the personal pages of the individuals concerned. Unless a researcher has been granted access to a personal page, this course of action is not available to them.

Social media has its benefits; it is a way of recording what is happening in a person's life today, but as Nick Barratt (2010: 268) has pointed out the information is limited in its historical value due to its sometimes unremarkable content. However, it is a form of personal archive that may be useful if an easy method of searching becomes possible in the future. Genealogists and family historians who are aware of and connected to family members on social media can keep up to date with their events, occupations, illnesses, hobbies, holidays, and personal opinions. It is not the preferred method of creating a family tree and archive, but it is a starting point to ask questions and request further information such as scanned copies of documentary evidence. This can then be recorded using traditional genealogical methods (Barratt 2010: 11–22; Adolph 2008: 21–23, 25).

The establishment of a place to put personal information for the benefit of family or society in the future is suggested by Nick Barratt (2010: 265–276) who favors a method of creating a personal archive using an online platform. This becomes a place for individuals to store their personal documents, photographs, memories, and family stories. It can be shared with family and the community, and this can be done by personal choice.

Privacy Concerns on the Web

Social media has changed society's views on privacy and what is acceptable to share with friends, family, and the public. It appears that people are more willing to share on social media, intimate details that would once have been kept private, but they are also concerned about an invasion of their privacy. In their research genealogists and family historians are not only creating records about themselves but are including others in their data collection and published results. Researchers who are using social media to add people and their personal information to a family tree must be aware that although it may be posted online, this is not deemed to have permission to share via a published tree or story. It is a usual genealogical practice not to publish data about people born less than 100 years ago or those still living (Paton 2011: 4), and to seek written permission before adding anyone to an intended publication. There are other privacy concerns such as family secrets and sensitive issues that need to be accommodated and should be considered by genealogists and family historians, as well as taking precautions against invasion of privacy and identity theft. Privacy settings on social media and subscription websites can be adjusted to suit the user and the needs of their individual family members (Barratt 2010: 275–276; Paton 2011: 4). These should also be respected in online and print publications.

Users of social media and subscription websites should also ensure they read and understand the terms and conditions of use before committing themselves (Barratt 2010: 275–276).

International Perspectives

Websites for Genealogists

The Web has a global reach, and it is possible to discover resources that archaeologists can find useful for their research on the same websites used by genealogists and family historians. This is because these researchers don't always confine their sources to just birth, death, and marriage certificates but use a variety of documents from archives and other documents such as land deeds, maps, military, and immigration records. The purpose of this is to broaden the details beyond the sometimes mundane, chronological data found on a family tree, thus enriching the family record with a social history (▶ "Genealogy, Its Relevance to Archaeology").

A simple Web search using the words "genealogy resources" will yield over 2 million results, and the word "genealogy" yields over 32 million. Not all will be useful for archaeologists, but it will reveal many that are worth investigation when the search is narrowed to specifics. Websites such as the National Archives ARCHON Directory (Barratt 2010: 98; Paton 2011: 8) provide links to archives within the United Kingdom and overseas and are a valuable resource for both genealogists and archaeologists. Libraries and genealogical societies can also provide a list of links to suitable family history websites, as will most recent genealogical "how to trace your family history" books and magazines. Archaeologists should consider taking advantage of these directories and links and to other sites known as "gateway sites" to access further resources.

A gateway site can provide links to other online sites (Paton 2011: 4). One of the largest genealogical gateway sites is Cyndi's List of Genealogy Sites on the Internet (Barratt 2010: 39; Hicks 2011: 9). This site is categorized alphabetically and cross-referenced and allows users to suggest new genealogical links for consideration. The site also includes thousands of links to genealogical and historical resources in various countries that are of interest to archaeologists, such as newspapers, canals, rivers and waterways, cemeteries, DNA, migration, land records, libraries, archives, museums, maps, and research methodology.

Genealogists also use the Web to access historical information and check dates, old place names, and conversions such as weights, measurements, temperatures, and currency and language translation to obtain the gist of foreign language letters and documents (Lynch 2008: 87–101). There are also discussion forums and blogs that genealogists use to share their research or ask questions (Paton 2011: 186–187).

Education for Genealogists

Online genealogical studies can be undertaken at universities and colleges allowing students to enroll at their educational institution of choice providing they meet the enrolment requirements. In some courses students are granted access to genealogy subscription websites and often engage in the study by researching their own family. There are many benefits of online courses because students may be able to study at a distance relatively inexpensively; the limitations are the lack of face-to-face contact with lecturers which for some students is a negative if they need support and are more productive with guidance (▶ "Genealogy, Its Relevance to Archaeology").

DNA Testing

DNA testing is now very popular with genealogists and family historians who are participating in autosomal, mitochondrial, and Y-DNA tests with various testing companies (Ancestry 2018; Family Tree DNA 2018). Results are compared with other people who have also tested, and they communicate with each other via online DNA forums within the company site. They also communicate using forums on social media. All these forums have a common connection such as country, family name, or genetic similarity.

Future Directions

No longer restricted to resources in their own country, the Web has made it easy for genealogists and family historians to research their ancestors and extended family. They are enjoying a proliferation of documents that have been provided by a worldwide network of archives, libraries, societies, businesses, subscription websites, and other individuals. Once located many of these records can be downloaded or their details taken in a relatively short period of time. Researchers now spend their time searching, cross-referencing, building their resources and family trees, and communicating over the Internet instead of travelling to repositories or writing letters, paying fees, and waiting for the results. Today's genealogists and family historians get better value for money because many resources are free and even a subscription or pay-to-view website is relatively inexpensive.

Gateway sites with their diverse links and international reach have shown researchers the potential for other kinds of resources that are available to them, and archives that have provided cross-links with other archives are doing the same. These sites have links to resources that are of use to genealogists and family historians, and there may be some that are of use to archaeologists.

Genealogy societies, universities, colleges, subscription websites, and individuals are continuing to educate genealogists and family historians on best practice, and this is available via online courses or discussion groups. This furthering of skills will enable the data created by these researchers to be more accurate so that GEDCOM files are more reliable.

Educational institutions and genealogy societies need to provide the support to genealogists and family historians regarding privacy, copyright, and due acknowledgment as more of them write their family histories and publish on the Web. They may also wish to consider a peer-review process before publishing articles in their journals both online and in print.

As more records become available on the Web, genealogy societies will continue to question the benefits of putting their records online. If they do so, they may lose membership, knowledgeable staff, and volunteers and become redundant.

Social media will continue to absorb the time and the minds of society who will persist in announcing special events on this platform. It will probably need the efforts of dedicated family historians to involve themselves in a more professional approach by contacting their family personally and asking for information, documents, and photographs. Online personal archives may become a popular pastime and provide an insight into the social history of the twenty-first century.

DNA studies will continue to fascinate society and may prove useful to archaeologists and anthropologists in the future as more people are tested and involve themselves in country, ethnic, and name studies among others.

Archaeologists may have no need for a genealogical family tree for their study, but some of the resources that genealogists and family historians use may be of value to them. There are many books written about genealogy and the availability of resources on the Web that are worth investigation, and if archaeologists examine them bearing in mind the limitations, they will find many that are of benefit.

Genealogy, Its Relevance to Archaeology

Doreen B. Kosak
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Genealogists and family historians can produce records that are a useful resource for archaeologists. These researchers trace ancestral lines of descent. To do this they use several different resources which may include but are not limited to archival records, their own or other family knowledge, oral histories, and memorabilia such as a family bible, medals, photographs, diaries, letters, and other written works. Their research may include data from several countries and take many years to complete. An inquiring mind and patience are needed to piece together the evidence necessary to create a genealogy or family history.

Most family genealogies and histories are not about the wealthy, well known, famous, or infamous. This means that the stories that are uncovered are not necessarily recorded in history books other than as a general reference to "the people," "the inhabitants of," or "ordinary folk." The contributions of these people to society by their work, civic duty, military service, or roles as family members often go unacknowledged except in the oral histories of their families. A consequence of genealogists and family historians compiling genealogical studies is the creation of a record of the lives of past populations as they attended to their daily activities, and as such they are providing a social history of the time.

Definition

The Macquarie Dictionary (2018) states that "genealogy (is) an account of the descent of a person or family through an ancestral line", and "the investigation of pedigrees as a department of knowledge." The word is Middle English which descends from the Late Latin word *genealogia*, which is derived from Greek meaning "tracing of descent."

A genealogist is a person who is either self-taught or tertiary trained, working in the field of genealogical research for others usually for a fee but not always. Some genealogists begin their career by researching their own family's genealogy, and because of their experience, they progress from there to working as a professional researcher. They are usually a member of a genealogical society and abide by a code of ethics. Occasionally genealogists give lectures about their specialty both locally and overseas, write books about genealogical research, or teach.

Family historians usually conduct genealogical research about their own family; they may also be self-taught, but increasingly like professional genealogists, they can further their knowledge and research skills by undertaking courses now offered at universities, private colleges, or genealogy societies. Family historians are often known as the "family genealogist." They undertake research on behalf of their family, collating the information, creating family trees, and sometimes publishing the results in the form of charts or books either in print or online. They may work

in collaboration with other members of their family both locally and overseas. Over time they acquire many skills and experience researching in archives and libraries, and become familiar with the history of the occupations, journeys, and places that involve their ancestors.

Historical Background

In the past, wealthy families kept genealogical records for reasons such as proof of lineage for marriage purposes, entitlement to birthright, or inheritance of property (Barratt 2010: 28). As people ventured to other parts of the world in greater waves of migration, their descendants have taken a growing interest in the origins of their ancestors resulting in an increasing number of family genealogists in the twentieth century. Before the emergence of the Internet, it was customary to either conduct the search yourself or engage the services of a professional genealogist. If an overseas search was necessary, then communication occurred by letter with time and cost making it prohibitive for some. Accordingly, most genealogical research was undertaken by literate people and those with considerable leisure time.

Genealogy societies developed due to the interest of genealogists and family historians who were willing to volunteer their time to create the resources needed to find out about their family history, and assist others to do the same. This initiative has resulted in the compilation of a vast amount of records suitable for genealogical and family history research. Society libraries and archives have grown and so have the collective knowledge and experience of those involved in maintaining them. In more recent times, much of this material has been digitized and put online for easy access via the Internet.

Genealogy society members come from all sectors of society; however, today's societies include among their membership a greater number of former academics and other professionals with tertiary qualifications such as historians, archivists, teachers, medical personnel, librarians, accountants, lawyers, engineers, and business owners. They will often apply their expertise to assist others or to create society resources suitable for family history research. They may be able to read Latin or old handwriting or have foreign language skills. Lawyers may interpret old wills, and architects assist with house and building plans. Teachers may take photos of schools and create an archive, and social workers or medical personnel may compile and maintain destitute asylum or old hospital record indexes. Others apply their skills to maintaining cemetery records, shipping records, or focusing on countries or localities. Their scholarly approach to research, referencing, and writing results in their work being a reliable contribution to the body of social historical knowledge (Triolo et al. 2017: 8).

Primarily a hobby for many and an occupation for relatively few, genealogy and family history have become a large-scale commercial activity and an alternative historical archive and human resource for other disciplines such as archaeology.

Key Issues/Current Debates

One of the key issues in genealogy is the accuracy of the research and recording process; if it is not done correctly or the research is not thorough, much time, money, and effort can be wasted tracing the wrong family over several generations. It is fortuitous when a mistake is found, but by then many years may have passed, and published charts and books will necessitate correction. There is a research and recording process that genealogists follow to lessen the chance of error.

Researching and Recording: The Process

Genealogists begin their research by working from the known to the unknown. For example, they may begin with themselves and work back through time recording their parents' details and then grandparents, great-grandparents, and other ancestors in turn (Adolph 2008: 14; Barratt 2010: 11). As the research proceeds, they record other members of the family, siblings, uncles, aunts, cousins, and partners. Vital records such as birth, death, and marriage certificates are the primary sources that give names, dates, and places of these events and

form the basis of the family tree. Depending on the requirements at the time, these records will often give names of the parents and occupation of the father and names of any witnesses. Archives, libraries, newspapers, letters, bibles, and wills are some of the other documents searched for evidence of family; this expands on the basic data and adds to the family story. Information should be confirmed by two or more sources, and these should be noted and referenced. Any inconsistencies should be question-marked for further research.

Best practice recommends keeping thorough and accurate records, and there are some conventional ways that genealogists do this. A record of searches and results both negative and positive including sources are logged in a logbook or a computer database, and should include names of the archive or document searched and the date. Speculation that is not backed up by documentary or other verification is discouraged, but inevitably some sources will be unverifiable or incorrect due to the way the document was created. For example, a name may be mispronounced by the informant and recorded incorrectly, or the exact date or place forgotten due to the veracity of the memory, or information may be falsified for various reasons. The genealogist's logbook becomes a useful tool for future research and equates with an archaeologist's field logbook.

There are recording conventions (Adolph 2008: 22; Barratt 2010: 23) that genealogists adhere to when creating charts; these simplify the data, clarify any ambiguities, and will make following a person or a family easier. It is wise for archaeologists who are creating genealogical charts for their historical reports to use these conventions, or alternatively engage the services of a genealogist to do the research and present the chart so that the work can be interpreted correctly by others in the future.

Computers and Genealogy

The once time-consuming job of creating paper records and charts has now been automated by genealogical computer programs. These programs are becoming more sophisticated in their ability to store genealogical data such as names, dates, and other information about people on the family tree. There is also the ability to indicate a source document and to attach a scanned or downloaded copy of the document or photograph to the individual concerned. Depending on the program, audio files and video files can also be attached, and some programs are able to link to a geographic locator or external website. Various family history charts and reports can be created and printed. These can be likened to a biographical index displaying details about names, dates, events, and places in a narrative; however, they do not replace a fully researched and written family history.

Genealogists can share their computer-generated family trees by using family history Genealogical Data Communications (GEDCOM) software, either by emailing the tree to another researcher or by uploading it to their own or an external website (Barratt 2010: 33). This allows others to view the tree and download it, adding it to their own if matches are found. There are advantages and limitations to using genealogical data created by others, and these are discussed in ▶ "Genealogy on the Web: Benefits and Limitations".

Writing Family History

The completed genealogical chart while useful and interesting provides the record of the family: the names, dates and places of birth, marriages, and death. However, it is the additional information about occupations, achievements, military service, travel, sports, hobbies, health, wealth, and possessions that adds flesh to the genealogical skeleton, and thus it becomes a more useful resource for archaeologists.

After compiling their genealogies, some family historians publish their research in print or online. This can take the form of a family history, family biographical index, biography, autobiography, genealogical chart, or a diary transcription. It may also include a substantial amount of detail about migration or the local history of a town, place, or building such as a school, hospital, or civic center. However, like some early local histories (Triolo et al. 2017: 7), family histories may be limited in their readability and consist of chronological historical data and names with an uninspiring storyline. Poor referencing and unstated sources prove to be another limitation

that reduces the value of the information. However, while early family histories may have their limitations, they can be a guide or starting point for further research.

Some genealogy societies are addressing these limitations by providing support to their members by way of a writing group; they may also convene genealogical research, recording, writing, and publishing seminars; publish "how to write your family history" books; or add them to their collections. They invite entries into their family history book awards (Wilson 2018) and encourage authors to donate a copy of their book to their library. Publishing and printing houses are more aware of the growing interest in writing among family historians, and they are accommodating their needs by hosting seminars and dedicating staff to service them. While family histories will have greatest readership among family members, the works are a valuable contribution to the body of knowledge of the social history of a time and place, and as such they are receiving more consideration from historians (Dymond 2016: 158–160). It is in this context that archaeologists can review these published works when they are researching social history.

The Importance of Meaning

Heirlooms and memorabilia, photographs, archives, and property are among the possessions that hold special meaning for family historians who may record their significance in photographs or stories. Sometimes the memorabilia become part of an inheritance remaining in the family for several generations, and the stories of its ownership and when and how it was used are passed on. This puts the memorabilia into an historical context and gives it a place within the family as a direct conduit to its original owner.

With a desire to imbue experiential response into archaeology, Michael Shanks (1991: 58) suggests that by exploring what an object meant to its owner, value can be attached to a trivial find. By communicating with family historians, archaeologists may derive better insights into social customs, traditions, and the meaning of their possessions or places, thereby coming to better conclusions about their archaeological investigations.

Researching Family Property

The types of records that family historians keep in their collections or access at the archives sometimes concern the homes, properties, or farms that their ancestors owned or lived in (Adolph 2008: 148–155; Barratt 2010: 114–120). Photographs, plans, and land titles are some of the records they may have in their possession. They may also have a more intimate knowledge of the property if they resided there such as: information such as the location of buildings, outhouses, rubbish tips, or other features. Some places may have been a part of the original settlement of an area. Family historians may also include the family home in their written historical account of their ancestors (Triolo et al. 2017: 8). This detailed knowledge may provide useful information to archaeologists researching a home, farm, or township, especially if there are plans and photographs included.

Cemetery Indexes and Photographs

Cemetery headstones provide genealogists with critical evidence about their family members and occasionally may also list multiple members of the same family. The deceased person's name, date of birth and death, and sometimes other useful information about their life such as occupation or military service are obtained from them. Because of the importance of headstones, some genealogy societies have a dedicated team of volunteers who have photographed and recorded the inscriptions over time, preserving the data in their archives. These photographic indexes are a valuable resource to archaeologists who are studying historical cemeteries especially where headstones have been lost or damaged due to time, vandalism, or the contemporary practice of gravesite reuse. Contact with the genealogical community may also reveal descendants who are willing to share information that will assist in archaeological studies, such as their ancestors' social status, occupation, or health.

DNA in Family History

The genealogy community is taking advantage of the availability of DNA tests. For some, it is to find genetic matches to further their research or confirm lineage where the paper trail is lacking, and for others it is the eagerness to find lost family

members due to adoption, abandonment, or, in the case of Indigenous Australians, forced separation due to Commonwealth government policy (MacDonald 1995: ix). Many people are simply curious about their genetic origins. Findings will sometimes provide unexpected results, for example, a Y-DNA test may disclose a paternity anomaly and disprove a well-researched and well-referenced paper trail. Some genealogy societies provide a DNA support group (Genealogy SA 2018) for their members who then become familiar with the terminology and tests, and may also share their results with DNA projects that focus on a surname, region, or country or with the National Geographic's Genographic Project (Family Tree DNA 2018).

The discovery that caught the attention of archaeologists, historians, scientists, genealogists, and the public in recent times was the collaborative efforts of the team involved in the archaeological excavation and scientific study of the remains of King Richard III. The merit of both genealogical research and DNA was effectively used to confirm the king's identity by establishing a genetic link via mitochondrial DNA inherited through female lines of descent. Working from the known to the unknown using historical genealogical charts, two descendants of Richard's sister, Anne of York were traced and genetically tested, and their mitochondrial DNA matched that of the skeleton. Further tests were done on fragmented Y-chromosome DNA to find a match with five patrilineal relatives without success; however, radiocarbon dating and other visible factors together with the DNA match provided evidence that the remains had a high probability of being those of King Richard III (King and Schurer 2015).

International Perspectives

It is evident from the worldwide spread of genealogical activities (Adolph 2008: 7) that people are curious about their ancestral origins. Through the efforts of the genealogical community, archives, subscription websites, and the Internet (▶ "Genealogy on the Web: Benefits and Limitations"), access to resources is easier and has enabled many more people to research their family's history. People are also travelling to places where their ancestors originated from and are combining research or education with tourism (Adolph 2008: 6).

Genealogy Societies and Regulatory Bodies

Each country or region may have one or several genealogy societies or regulatory bodies that service the needs of the genealogical community and the public. They are often not-for-profit organizations with a formal and legal constitution that dictates their purpose and conduct and that of their membership who may be bound by a code of ethics. A search on the Internet will provide a list of the organizations in each country. The following are some examples of the services provided. In the USA, the Board for Certification of Genealogists (BCG) (2018) has a code of ethics, promotes high standards, and provides certification to candidates who attain competency. In 2014, the BCG published a book of genealogy standards. The Society of Genealogists (n.d.) in London was established in 1911; among other support, it provides educational lectures and workshops and has a substantial library. In Australia and New Zealand, genealogy, family history, and other allied groups are supported by the Australasian Federation of Family History Organizations Inc. (AFFHO) (2018) which was established in 1978. Among its roles, the organization promotes family history research, provides a code of ethics, lobbies the government when necessary on issues relating to access of family history information, monitors international trends in genealogy and family history, and disseminates information to its members. The organization also initiated National Family History Month held annually in Australia, and supports the Australasian Congress on Genealogy and Heraldry held in a different city in Australia or New Zealand every 3 years. This congress provides worldwide perspectives through international speakers.

Genealogy societies network with each other as well as with other archives and history-related

groups. This association can be with both local and overseas organizations, such as the German-Australian Genealogy and History Alliance (2017). This member organization encourages the sharing of research and resources about the history and heritage of German-Australians. It is a partner of the International German Genealogy Partnership whose members are derived from genealogical organizations and societies in the USA, Germany, Canada, England, Australia, and Brazil. The research and resources generated by these organizations contribute to the social history of their region and are shared at conferences.

Qualifications and Professional Development

There are many courses that are developing professionalism in genealogy studies internationally. For example, in Australia, the University of Tasmania (2018) offers a fully online course of eight units with a focus on introducing students to family history research. The subjects cover researching convict ancestors, military records, and oral history; writing family history and photo essays; and interpreting family memorabilia and putting it into historical context. In the UK, the University of Strathclyde (n.d.) offers postgraduate studies that can lead to professional recognition and membership of the Association of Scottish Genealogists and Researchers in Archives (ASGRA) and the Association of Genealogists and Researchers in Archives (AGRA). Graduates may also be included on the Register of Qualified Genealogists (RQG). As students progress through the course, they not only study sources and genealogical methods and practice in the UK and Ireland but also in Europe, the USA and Canada, Australia, and New Zealand, Jewish genealogy and DNA. The National Genealogical Society (2018) in the USA gives several options for furthering professional studies in genealogy, for example, there is a certificate course at Boston University, and the Department of History at Brigham Young University in Utah offers a BA in Family History/Genealogy program where genealogy can be taken as a major or minor.

Future Directions

The future direction of the genealogical community will be driven by several determinants: genealogists and family historians, genealogy societies and their affiliated member organizations, archives, libraries, subscription websites, universities, and the public. There is an opportunity for other disciplines such as archaeology to add value to the development of genealogy and family history.

The Future for the Family Historian

The Internet has changed the way that genealogy and family history are researched and allowed more people to become involved in its study. Some challenges for family historians are the same as those for genealogy societies and organizations, for example, keeping up with technology and the future preservation of records.

If they are not already doing so, family historians should become familiar with genealogy best practice when researching, recording, and presenting results. If they are using the information and genealogies of others, these should be scrutinized and the sources checked for accuracy. The same applies to information found on the Internet because not everyone has scholarly research skills and some of their findings may be incorrect.

For archaeologists, the benefits of joining a genealogical society are found in the support provided to researchers. The genealogy community is active both locally and internationally, and by attending seminars and conferences, family historians will keep abreast of genealogical knowledge. Many family historians have already taken advantage of formal studies, and others are honing their literary skills to improve the quality of their research and writing. Both will make the future of their work more reliable as a contribution to social history.

There are some important aspects of genealogy that may be missed in the eagerness of creating a family tree or history and publishing it. For example, there are privacy laws, and so details about living people should not be published without consent. Family historians should also be aware

of the impact that the disclosure of sensitive information may have on some people. Copyright laws and due acknowledgment protect the work of others. Family historians will do well to abide by a genealogical code of ethics.

DNA is probably an unexpected and interesting way to do family history research, and is fast becoming a popular activity. However, once a match or close match is found, there still involves a considerable amount of archival research, following the paper trail to ascertain the connections.

Genealogy for the family historian is not going to slow down; what will change is the way it is conducted and the number of people undertaking it – the advent of the Internet has proven that. What must happen is what has been said before, a more discerning approach to research, recording, creating charts and writing, if the information is to be taken as an historical account of the past thereby becoming more useful as a social history for genealogists, archaeologists, and historians.

Challenges and Future Directions for Genealogy Societies and Organizations

Some societies have been operating since the beginning of the twentieth century, and over this time societies with an active membership have amassed a large collection of resources such as books, school, hospital and destitute asylum indexes and records, photographs, maps, newspaper cuttings, eulogies, and published family histories and genealogies. They have become an alternative repository for the social history of a place. Some of the challenges they face into the future are the undertaking of the preservation of their archives and resources by scanning and digitizing the records, then creating adequate and accurate indexes for ease of use, and finally using archival quality storage of the records.

Future challenges include keeping up to date with new software so that these records are available in a useable format for the future, and making decisions as to whom they make these records available, for example, allowing full access to members but nonmembers have access to indexes only. Societies need to find ways to remain relevant in the age of the Internet where resources are so easily accessed from home. They can do this by educating genealogists and family historians on best practice methods of research and recording so that their work is accurate, referenced, and as reliable as possible. They will also be supporting the genealogy community by continuing to keep an international perspective and ensure that the free-flow of information between countries is enabled via visiting speakers, congresses, and exhibitions.

Communicating with the public regarding the value of family history and its archives, and building closer relationships with other community groups including Indigenous people and new migrants will lead to better social inclusion, and thereby diversify the records and sources for genealogical research in the future. The value of genealogical records, research and expertise will be further understood if the genealogical community builds closer relationships with other archives and libraries. Also, by assisting others such as archaeologists and historians with their research, and at the same time, informing genealogists and family historian about archaeological practice and how both disciplines can benefit one another.

Genealogy and Archaeological Research

Genealogy is a community initiative, a desire on the part of family historians to reach into the past to find out about their origins and record and preserve it for future generations. Archaeologists may play a role in how genealogy progresses in the future by involving the community in the historical (Diaz-Andreu and Ruiz 2017) or practical aspects of archaeological studies. Larry Zimmerman (2014: 19) proposed that rather than merely studying the distant past, archaeologists should be more politically active in their practice by working with stakeholders and non-archaeologists. Together they may change societal attitudes or government policies. This adds a political dimension to archaeology in contemporary society. This adds a political dimension to archaeology in contemporary society. Whether the genealogical community wants to become involved in politically charged issues is a matter that they may need to consider, but they are able to provide archaeologists with some of the evidence necessary to give insights into community and social issues. This

evidence may be in the form of genealogies, compiled records, archives, DNA studies, knowledge and personal connections both local and overseas, and intimate insights into social history often unavailable in the usual historical studies and literature.

By communicating their research, archaeologists bring a tangible element of history to an audience that has considerable interest in the results. Archaeologists can publicize their research questions among the genealogical community and request information or support in their historical research. If forthcoming, this support may take the form of interviews, on-site discussion, and access to photographs, documents, and family memorabilia. Genealogy societies allow day visitors for a fee, and a visit to the genealogical or family history society or library in the city or town in the region of their study will give access to both archives and other resources including people with an intimate knowledge of those records. After the archaeological investigation is completed, the results can be presented at genealogy society meetings, seminars, and congresses thus bridging the gap between the community and archaeology and thereby promoting a better understanding of the value of archaeological research. Genealogy societies generally have a journal in which archaeological results can be published of historical, genetic, or social interest to genealogists. With better communication between the two parties, misconceptions can be corrected and questions answered. Genealogists and family historians may have the who, what, and when facts that are not recorded in history books because they were deemed unimportant by historians, and archaeologists can provide the evidence to establish a probable theory of a way of life or use of a place in the past.

Genealogists and archaeologists research people and places over time. Archaeologists are concerned with the material remains that people and societies produce or leave behind, and genealogists are concerned with finding out about their ancestors and family, who they were, what they did, and where and how they lived in the past. Like archaeologists they research in archives, obtain oral histories, question, travel, and examine possessions and documents for clues, writing up their results in the form of genealogical charts and family histories. Genealogical research is a valuable contribution to the social history of a place whether it is a village, town, city, or country, and archaeologists may obtain useful support from genealogical resources and the people that create them. Often genealogists can provide the missing piece of information that can indicate where an archaeologist should begin to search, not only in the records but also in the physical space or place. There is an opportunity for the future direction of both disciplines to assist one another in coming to conclusions about the past.

Genetics of Animal Domestication: Recent Advances

Pamela Wiener
The Roslin Institute, R(D)SVS, University of Edinburgh, Easter Bush, Midlothian, UK

Introduction

Although domestic species of plants and animals were key to the development of Darwin's theory of natural selection and featured prominently in his books, domesticates have not recently been central to the study of evolution and evolutionary genetics. However, recent developments in molecular genetics tools and techniques are changing this, renewing interest in the genetics of domestication and the use of domesticated species as model organisms for addressing general evolutionary questions (Wiener and Wilkinson 2011). This entry reviews how current genetic analyses are clarifying our views of animal domestication.

Key Issues and Examples

Detection of Selected Genes or Genomic Regions

Selection has clearly been a key force in shaping the histories and phenotypes of domesticated animal species, but the processes by which this has happened have only recently been addressed. Various approaches, many borrowed from human genetics, are being used to identify regions of the genome carrying signatures of selection, which thus may be associated with changes underlying domestication and breed development. One approach adopted in domestication genetics is to examine patterns of diversity around candidate genes, which based on their function are likely to have been targets of selection. However, most techniques have been developed or extended to exploit the current availability of dense genome-wide marker panels, allowing scans of the genome

that search for patterns consistent with selection. These include tests identifying breed differentiation, reduced genetic diversity, extended linkage disequilibrium (statistical associations between loci), or non-neutral allele frequency patterns in specific genomic regions as well as associations between genotype and domestication-related phenotypes.

The application of these various population genetic approaches has identified several classes of genes that appear to have been under selection. The strongest evidence for genetic changes associated with domestication and breed development has been found in genes related to animal color and pattern. Selection on a number of genes has resulted in a wide variety of colors and patterns across breeds, as evidenced by genetic differentiation and frequency spectrum patterns near these genes, including *MC1R* (melanocortin 1 receptor), which is associated with the switch between eumelanin (brown/black) and pheomelanin (red/yellow) pigment production. Although the closest wild relative to the domestic pig, wild boar, carry substantial neutral variation at this gene, nearly all individuals genotyped so far express the same *MC1R* protein, resulting in a coat in different shades of brown (Fang et al. 2009; Li et al. 2010). In contrast, there is reduced neutral variation in domesticated pigs but at least 10 different *MC1R* proteins, associated with a wide range of coat colors (Fang et al. 2009). Variation at *MC1R* is also responsible for independent evolution of the black coat in both European and Asian pigs, which carry different variants at this locus (Li et al. 2010). The selection in Chinese pigs appears to be due to the preference for the black coat in animal sacrifice rituals during the Neolithic period. There is also a suggestion of selection acting on several other color and pattern genes, including *KIT*, which affects melanocyte migration from the neural crest to the skin and is associated with spotting, belting, and other coat patterns in pigs, horses, and cattle. Evidence for selection near the *KIT* locus has been found from allele differentiation patterns between breeds of sheep (Kijas et al. 2012) and cattle (Stella et al. 2010).

Another group of genes that show signatures of selection are related to growth, size, and body conformation. The *GDF*-8 (myostatin) gene has been associated with a variety of muscle conformation phenotypes in cattle, sheep, and dogs. A dramatic reduction in genetic diversity, indicative of selection, has been identified near this gene in cattle breeds with exaggerated muscle development (double muscling) such as the Belgian Blue and Asturiana de los Valles (Wiener and Gutierrez-Gil 2009), and there is strong differentiation between Texel sheep, a highly muscled breed, and other sheep breeds (Kijas et al. 2012) near this gene. The region including the growth hormone receptor gene (*GHR*), associated with growth and cattle production traits, has also been highlighted by both breed differentiation and within-breed selection scans of the bovine genome (e.g., Hayes et al. 2009). The regions surrounding *IGF1* and *HMGA2*, two genes associated with body size, show signatures of selection in dogs (Sutter et al. 2007; Akey et al. 2010; Boyko et al. 2010).

There is limited evidence of selection signatures on genes related to fertility and reproduction. The clearest example is that of the thyroid-stimulating hormone receptor (*TSHR*) gene (Rubin et al. 2010), which is involved in metabolic regulation and reproduction. The region encompassing this gene was almost completely identical over a 40-kilobase segment across all domestic chicken lines. This gene also showed evidence of differentiation between sheep breeds (Kijas et al. 2012).

A final group of genes that show strong evidence of selection-imposed changes are those associated with skeleton- and skin-related phenotypes. One of the strongest signals of breed differentiation in a genomic scan of 10 dog breeds (Akey et al. 2010) was seen near the *HAS2* gene. This signal was seen only in the Shar-Pei breed, characterized by a distinctive skin folding phenotype not seen in other breeds. By comparing groups of dog breeds with distinct characteristics, genomic regions associated with ear shape and tail curl have also been located, although the underlying genes have not yet been identified (Boyko et al. 2010). Similarly, a region on sheep

chromosome 10 shows a strong signal of differentiation between horned and polled (hornless) breeds, and it has been suggested that mutations in the *RXFP2* (relaxin/insulin-like family peptide receptor 2) gene may be associated with loss of horns in this species (Kijas et al. 2012).

Detecting Demographic History

Genetic data is also helping to unravel the demographic history of domesticated breeds. Linkage disequilibrium (LD) declines with the genomic distance between markers; moreover, the shape of the relationship provides information on population history. LD patterns can be used to infer past effective population size (the number of individuals in an idealized population that would have the same rate of genetic drift as the actual population) and demographic events, as the LD between tightly linked markers reflects effective population size further in the past than the LD between loosely linked markers.

The relationship between LD and genomic distance has been exploited in a number of studies to estimate past effective population sizes of domesticated animal species. The cattle HapMap study (Gibbs et al. 2009) analyzed dense genome-wide SNP data from 19 breeds. They found that the decline of LD with distance between markers was generally rapid but varied between breeds. In contrast to the pattern seen in humans, effective population size appears to have declined recently for all breeds, presumably due to bottlenecks associated with domestication and breed formation. Comparing LD-distance relationships across breeds can be used to understand the different breed histories. The N'Dama (an African taurine breed, humpless cattle originating in the Middle East) had the highest LD values of all breeds at short distances, indicating a small ancestral population, whereas the three indicine breeds (humped cattle originating on the Indian subcontinent) had lower LD than the other breeds at short distances, indicating a relatively large ancestral population compared to the taurine breeds. This characterization of indicine cattle is consistent with findings of higher nucleotide diversity in indicine than taurine breeds (Gibbs et al. 2009).

An LD-based approach has also been used to reconstruct the demographic history of dogs. The publication of the first genome sequence for the dog and the initial set of dense SNP genotypes for dogs from various breeds allowed an assessment of LD patterns both within and across breeds (Lindblad-Toh et al. 2005). The decline in LD with respect to physical genomic distance for the overall dog population was rapid, falling quickly to low background levels. This relationship is consistent with a domestication-related bottleneck ~5,000–9,000 generations ago, based on comparisons with simulated data (Lindblad-Toh et al. 2005; Gray et al. 2009). In contrast, within most dog breeds, the presence of long-range homozygous haplotypes and high levels of LD over extended regions is consistent with a more severe contraction in population size 30–90 generations ago, at the time of breed-creation events. However, some dog breeds (e.g., Labrador Retrievers) do not have particularly high levels of LD (Lindblad-Toh et al. 2005; Gray et al. 2009), presumably because of their relatively large effective population size.

Introgression

Genetic data has also shed light on past introgression (hybridization) between breeds. Animal breeders often practice crossbreeding to introduce certain desirable traits for breed improvement. In the case of pig breeds, human-mediated crossing has influenced the genetic composition of European breeds (Wiener and Wilkinson 2011). In the eighteenth and nineteenth centuries, Asian alleles were introduced into certain British pig breeds to promote traits such as fattening and earlier maturation (White 2011). Molecular genetic studies have since provided evidence of this introgression. A study examining mitochondrial diversity in pigs revealed that a number of European commercial pig breeds carry Asian-like mtDNA haplotypes (Fang and Andersson 2006). Genetic introgression can also be non-human-mediated, such as gene flow between wild relatives and domestic populations. For example, Fang et al. (2009) found that a Chinese wild boar carried an *MC1R* allele common in European domestic pigs, presumably resulting from gene flow.

Future Directions

Although identification of the genes important in animal domestication and breed development is still in its early stages, some common themes have emerged. One is that there are clearly strong signatures of selection near a number of genes associated with coat color and pattern. There are also indicators that suggest selection on genes related to growth and body composition. For example, there is clear evidence in cattle and sheep for selection on the myostatin gene, associated with muscle composition, and several studies also suggest that there may have been selection in cattle on the growth hormone receptor gene, associated with growth rate and various production traits. In dogs, there is also evidence of strong selection on a number of genes associated with growth and skeletal traits, many of which are associated with breed-specific characteristics. Understanding the selection history of complex traits such as those related to behavior and milk production will require more extensive analysis. Genomic information has also provided substantial insight into the demographic and breeding history of domesticated animal species.

Genetics of Early Plant Domestication: DNA and aDNA

Robin G. Allaby
School of Life Sciences, University of Warwick, Coventry, Warwickshire, UK

Introduction

The evolution of domesticated forms of crops was associated with the transition from hunting-gathering to agriculture at various centers around the world. Genetics has long been used to study domestication to answer questions about the mode and length of the process. Ancient DNA has been used to add a temporal dimension to interpreting genetic diversity by providing evidence of past expansions, some of which failed, and direct evidence of the selection of traits associated with domestication. A major challenge of the field is to reconcile genetic evidence with archaeological evidence and to redefine what exactly is meant by the term domestication.

Definition

In the case of plants, the evolution of domestication involves the selection of a characteristic group of traits that are collectively termed the domestication syndrome. Typically, half a dozen or so traits occur in any one domesticated plant. These traits include the loss of shattering (the ability for a plant to abscise and drop its seeds), changes in seed size, loss of photoperiod sensitivity, changes in plant physiology, and architecture. A combination of genome-wide information and direct evidence from the DNA obtained from the archaeological record is being used to assess the molecular mechanisms underlying domestication syndrome traits, the pace of the transition and the strength of the selection processes involved to understand this human-plant interaction.

Key Issues/Current Debates/Future Directions/Examples

Understanding the evolution of domestication of plants is a subject that is interlocked with understanding the rise of civilization. In broad terms, there have been two extreme viewpoints about the origins of domesticated plants, and the debate is ongoing. The first viewpoint is that the evolutionary process was rapid, artificial selection was strong, and domestication events were infrequent and often geographically restricted (Zohary and Hopf 2003). Associated with this viewpoint is that predomestication cultivation was limited and that domesticated plants appeared as a package originally described by Gordon Childe as a "revolution." The alternative viewpoint is that the evolutionary process was slow, and domesticated forms appeared in parallel in different locations (Weiss et al. 2006; Willcox et al. 2008).

Genetic evidence based on early techniques initially supported a simple origin for most crops (Brown et al. 2009). A problem was that these genetics-based findings contrasted with emerging evidence from the archaeological record that suggested that predomestication cultivation occurred for substantial periods before the emergence of domesticated forms and also that the assemblage of the traits of the domestication syndrome occurred in a staggered manner over a considerable time period (Fuller 2007). Further evidence directly from the archaeobotanical record suggests that the selection pressures

involved for at least some of the domestication syndrome traits, such as seed size and loss of shattering, were low within the range of normal natural selection for both wheat and rice (Purugganan and Fuller 2011). While these initial differences between the interpretation of genetic evidence and emergent archaeological evidence were reconciled through computational models that established that the genetic data could be interpreted within the archaeological framework (Allaby et al. 2008), the debate about the pace of transition continues and is dominated in particular by consideration of cereals of the East and Near East (Abbo et al. 2011).

A similar series of developments have occurred in the understanding of the evolution of domestication at tropical latitudes. The types of plants domesticated in the tropics differ in character to those of temperate latitudes including a large number of arboreal and herbaceous species with large fruits or tubers. It has long been known that tree species such as sweet almond were exploited well into the Pleistocene by peoples of the tropics. This can perhaps be compared to the well-known exploitation of hazel nuts by Mesolithic peoples of temperate Europe; however, the latter are not considered a domesticated species. In the case of arboreal species, the domestication syndrome is subtler than for cereals often only being evident in the thinning of nutshells or fruit skins in the case of screw pines and loss of seeds in the case of breadfruit, for instance, which raises the question at what point a plant species can be considered domesticated. A variety of features such as dwarf habit, self pollination, and a "*niu vai*" fruit morphology have been identified in the case of the coconut, which has now been shown to have complex origins from genetic evidence (Bunn et al. 2011). Despite the acceptance of a long history of tree exploitation, little credence had been given to the exploitation of herbaceous species in the early Holocene, until recently. Archaeological evidence shows the exploitation of bananas, for instance, in the Papua New Guinea Highlands in the early Holocene well before what is normally considered the onset of cultivation in that region. The genetic evidence in this case shows an extremely complex origin of bananas involving the differentiation of subspecies of the diploid progenitor in the islands of Southeast Asia and western Melanesia, followed by hybridizations repeatedly producing sterile triploids which have the seedless syndrome trait, such as the Cavendish banana (Perrier et al. 2011).

As analyses have moved to the genomic level increasingly, the specific genetic mechanisms underlying some domestication syndrome traits are being understood for several of the major cereal crops (Fuller and Allaby 2009). In the case of rice, it is apparent that different traits appear to have originated in different geographic origins (Shomura et al. 2008). The scale of the genetic underpinning of domestication is also becoming apparent, and although the number of syndrome traits is relatively low, the number of loci involved appears to be high. For example, in the wheat 30–70 genes have been estimated to be involved, over 30 genes in sunflower, and 50 genes in maize (Peng et al. 2003; Wright et al. 2005; Chapman et al. 2008; Peleg et al. 2011). Such a large number of genes involved suggest that the evolution that is associated with domestication has been ongoing and that a rethink is required about what is meant by domestication and the relevance of the term "domestication event." In the past domesticated plants in the archaeobotanical record have been identified as such on the basis of one or two traits, particularly the loss of shattering trait, and the implicit assumption has been that other less visible traits are probably also present. However, the staggered arrival of traits suggests this is a simplification and that a discrete "event" might be better replaced with the concept of a "domestication trajectory."

The evolution of plant domestication has also been directly studied through the use of ancient DNA. This approach has been used to establish the presence of particular species at specific locations in the past, the temporal stability of phylogeographic patterns of genes, and direct change of DNA through time. For example, the presence of one wheat species in Bronze Age Greece where it no longer occurs established the occurrence of a failed expansion (Brown et al. 1998). On the other hand, the geographical distribution of alleles from maize compared between ancient cobs and primitive land races showed that there had been little change in South America over

the past millennium and that such phylogeographic patterns can be stable to the point of being indicative of initial expansions of the plant (Lia et al. 2007). Furthermore, studies in maize remains over time have shown the process of selection of domestication syndrome traits was staggered with some traits such as architecture being selected early and traits affecting flour quality being selected millennia later (Jaenicke-Depres et al. 2003). More recently, ancient DNA studies in plants have moved to the genomic level where extensive genome level evolution has been observed in cotton in the past few thousand years (Palmer et al. 2012). Such studies are leading to a consensus common to that based on extant genetic data that the evolutionary process of domestication is an ongoing trajectory rather than discrete event and that crops have and continue to change in their local habitats and in some cases represent local adaptation over thousands of years. In the coming years a more complete picture of the evolution of domesticated crops is likely to develop as new technologies are increasingly applied directly to genome change viewed through the archaeological record.

A recurrent theme in the discourse about the evolution of domestication is the level of consciousness there was in the human agency of selection. In one extreme view, early cultivators were highly aware of all "sports" (visibly mutant plants) that occurred in plant populations and judiciously selected for desirable traits. At the other extreme all traits arose through the unconscious actions of the cultivators. The former appears to lend itself to scenarios of more rapid selection, while the latter appears less restrained to a rapid or protracted process. The truth of the matter is likely to differ for different traits and species. However, understanding the mode of human agency will ultimately require the integration of archaeological and genetic evidence in meaningful and deterministic ways, which is possibly one of the greatest challenges that lie ahead.

Geoarchaeology

Christopher L. Hill[1] and George (Rip) Rapp[2]
[1]Environmental Studies Program, Boise State University, Boise, ID, USA
[2]Department of Geological Sciences, University of Minnesota Duluth, Duluth, MN, USA

Introduction

Geoarchaeology unites the study of the record of past human activity with the natural sciences. The geoscience approach in archaeology is used in a variety of ways, including planning and performing fieldwork and collecting information from the field, deciding on the most appropriate and useful laboratory techniques, and evaluating the long-term connections between humans and the environment. A diverse array of archaeological questions can be addressed by using earth

science approaches, including studies of environmental contexts, examining patterns of human use of the land and natural resources, predicting the preservation potential and location of archaeological sites, documenting site and regional-scale sedimentology and stratigraphy, identifying and describing raw materials, evaluating taphonomic processes and the dynamics of site formation, dating, and ecological integration. Conceptually, geoarchaeology provides a means to examine long-term linkages between human populations and other components of the geosphere and biosphere.

Definition

Geoarchaeology includes the application of earth science methods to archaeology as well as the broader study of long-term patterns of interaction between people and natural systems. From the 1970s to the turn of the century, there were many discussions in the American literature concerning the definitions of geoarchaeology and archaeological geology.

Operationally, geoarchaeology is the application of any of the many subdisciplines in the geosciences (e.g., sedimentology, geomorphology, geophysics). It uses the methods, theories, and knowledge base of the geosciences to solve archaeological questions.

Based on this approach, geoarchaeology is affiliated with environmental archaeology and Quaternary geology as well as physical geography. Because of this, geoarchaeological projects employ nearly all the geoscience subdisciplines, except those that are focused exclusively on pre-Quaternary research. For instance, structural geology (folds and faults) has largely a pre-Quaternary focus, although tectonic geology, the study of earth forces resulting in folding and faulting, is important in understanding recent vertical earth movements that affect sites of human habitation, such as changes in relative sea level at coastal archaeological sites. Tectonic earth movements also generate earthquakes which have had devastating effects on humans in many parts of the world and have done so in the past as well.

There are many examples where subdisciplines of the geosciences play a critical role in archaeological studies. The study of sediments and soils is a crucial component of archaeological excavations. Artifacts can be found in unaltered sediments or in deposits transformed by soil-forming processes. Geoarchaeologists apply standard descriptive techniques to the matrix enclosing artifacts and features in archaeological sites. This approach is extended to the study of raw materials that compose artifacts. Besides the use of a standard nomenclature to document sediment and soil color, particle size, and mineralogy, the physical and chemical properties are used to infer environmental conditions before, during, and after human use of a site. Thus, one role of a geoarchaeologist as part of an archaeological research project is to make observations, take measurements, and collect samples that will help make it possible to evaluate changing physical environments at a particular site.

The principles of stratigraphy are crucial for interpreting the natural and human processes that produce an archaeological site. Stratigraphic studies provide a way to document the changes over time at a particular site and also a way to connect sites on a regional or even global basis. These types of studies are linked to the description of sediments and soils, but they expand the application of these techniques both horizontally and vertically within an archaeological site. Stratigraphic principles are crucial for interpretations of patterns within a site and also between sites. Thus, they play a crucial role in relative dating and in landscape studies. The application of the principles of stratigraphy in archaeology also connects geoarchaeology with other historical sciences such as geology and paleontology.

Geomorphology, the study of landforms and their development over time, is used by geoarchaeologists to evaluate the long-term dynamics of landscape and climate change as well as site preservation. For instance, Das and Panjo (1999) give a geoarchaeological perspective on the late Holocene archaeological record of a region in West Bengal, in eastern India. Their work is an attempt to examine the evidence available for a landscape with a dynamic and

constantly changing river environment. Their study was centered on habitation deposits and structures from the early Medieval Period (eighth to twelfth centuries). The study of Quaternary landforms should be an important part of any archaeological field project. It is important to understand the physical setting and the resources that would have made a particular location attractive for human use. Additionally, geomorphic features can contribute to an understanding of the long-term, ongoing processes that have affected an archaeological site.

Soil science, and especially the study of ancient soils, contributes in many ways to archaeology. Soil formation, or pedogenesis, occurs when a parent material like sediment or bedrock is altered over time by climate, plants, and animals. In the 1940s, Hans Jenning used the acronym CLORPT to designate the soil-forming factors of climate, organisms (plants and animals, including humans), relief, parent material, and time. Over time, a vertical sequence of soil horizons can develop within the parent material, based on additions, removals, transformations caused by processes like weathering, and movement of materials within a profile. Geoarchaeologists study the properties in the soil horizons to provide information on the conditions that led to the soil, including human activities. The basic soil horizons include (from top to bottom) the A horizon, primarily characterized by the accumulation of higher amounts of organics, weathering, and loss by leaching or translocation; the B horizon associated with weathering and enrichment by illuviation; and the C horizon, consisting of unconsolidated parent material. Soils that were formed in the past are designated as paleosols and can be on the surface or buried. Soils are very valuable in archaeology because they typically imply a period of landscape stability or period of nondeposition and can be used to infer ancient environments. In some regions, buried paleosols can be traced across landscapes. For instance, the Brady Soil and Leonard Paleosol are associated with a period of landscape stability associated with human presence during the terminal Pleistocene and early Holocene on the Great Plains of North America (Holliday and Mandel 2006). Holocene mound sites also contain paleosols. For example, four buried soils were documented at a Harappa site in the Indus Valley in Pakistan (Schuldenrein et al. 2004). Harappa period structures dating to about 4000 BP were constructed above a paleosol with A-B horizons. Below this paleosol, there were other Holocene soils and soils developed within Pleistocene river deposits. Anthrosols, or soils resulting from human activity, can provide information on how humans used the landscape. These are often studied using geochemistry.

Geochemistry has been of great value in understanding archaeological sites. This geoarchaeological technique can be used to help interpret the sediments and soils within sites. Often, changes in the acidity (pH) of the site matrix can be used to explain the preservation or absence of certain artifacts. For instance, bones are commonly preserved in sites with sediments that have high pH levels (such as calcareous or carbonate rich deposits). One of the most useful geochemical approaches has been phosphate analysis. Phosphates are deposited in sediments and soils as the result of the decay of organic materials. Phosphorus in soils undergoes both fractionation and bonding to soil minerals. Because it bonds to soil minerals, it is not easily removed by water within the soil profile. Analyses of phosphates in archaeological sites can provide both chronometric and land use information. One example comes from the study of a large Mayan ruin in Yucatan, Mexico (Huston et al. 2009). Phosphate analysis was used to explain different lengths of occupation, variations in land use, and reveal the byproducts of maize processing. Thus, the geochemical analysis of sediments and soils provide a means for understanding human activity within sites but also can be applied to the study of broader-scale landscape dynamics.

A completely different aspect of geochemistry in archaeology is provenance studies, which can be used to help determine the source of raw materials used to make artifacts. Small changes in the abundance or types of chemicals found within artifacts can be used to determine their place of origin. Trace-element signatures can indicate geological and geographical sources of unaltered raw

materials such as native copper and host of minerals and rocks including obsidian. Less well known are isotope methods. Lead isotope studies have been used for decades with modest success to determine the source of copper used to make artifacts. Recently, the vexing problem of sourcing tin has been aided by breakthroughs in tin isotope methods (Haustein et al. 2010). Although tin-bronze was used in Greece by about 2600 BCE and in central Europe 400 years later, the source of the tin has not been determined. Chemical sourcing methods were applied to tin from several regions. The measured variations in isotope values made it possible to distinguish between ores made in three different regions. These kinds of techniques contribute to an understanding of ancient networks used for the trade and exchange of raw materials used to make artifacts.

Petrography, the technique of using a polarizing microscope to analyze the content of 30-micron-thick sections of rock, was invented by geologists over 100 years ago. In recent decades, this technique has been adopted by geoarchaeologists to study a variety of archaeological materials, such as stone tools and ceramics. A good example of such studies can be seen in a paper by Fitzpatrick et al. (2003) which demonstrated the use of petrography in establishing cultural interaction in Palau, Micronesia. This study examined pottery from both volcanic and limestone islands in the Pacific. An analysis of the materials in the pottery suggested that the ceramics were locally made and then transported to other islands. This example shows how geoarchaeological studies of raw materials can be used to look at patterns of exchange and interaction.

Microstratigraphy and thin-section analysis of sediments using micromorphology are ways of examining the taphonomic (depositional and post-depositional) processes that have helped in the formation of archaeological sites and to assess their stratigraphic integrity. Micromorphology involves first collecting an intact block of sediment from an archaeological site. In the laboratory, the block is impregnated with polyester resin and then sliced to make thin sections that are examined using a microscope. For example, the micromorphological analysis of sediments collected along the contact between Middle and Upper Paleolithic deposits at a cave in Germany revealed a sharp erosional contact between the two groups of deposits, thus indicating that no mixing had occurred. Thin-section study of sediments from a Paleolithic cave in France provided evidence of burning, trampling, and hearth-cleaning activities (Goldberg and Berna 2010). A micromorphological study of cave deposits in China with pottery dating to about 19,000 years ago (the Last Glacial Maximum) demonstrated that mixing and redeposition was negligible, lending support to the stratigraphic integrity and dating of the site (Wu et al. 2012).

Geophysical techniques are used by geoarchaeologists in situations where they cannot excavate or to study places they may not be able to reach on the ground. The most common use of geophysics in archaeology is in geophysical prospecting, often referred to as remote sensing. These techniques have proved especially important in broader-scale landscape studies. Parkyn (2010) used high-resolution geophysical surveying as a precursor to field studies, as a way to guide excavation in addressing the 120-year development of a late Victorian municipal park. Remote-sensing techniques are used to distinguish anomalies in the ground which may indicate the presence of archaeological features.

In terms of dating, archaeologists usually are somewhat familiar with carbon 14 dating but geoscientists have played only a minor role in these methods. Chronometric dating methods such as the use of carbon 14 provide a numerical estimate for the age of an archaeological site. This is in contrast to stratigraphic dating which (in the absence of correlation with other dating methods) provides only an understanding of the relative age of an archaeological deposit. Several dating techniques have been developed that can be used to analyze materials associated with archaeological sites. Besides carbon 14, the major dating techniques used by geoarchaeologists are U-series and K-Ar dating. While carbon dating has been extensively used to date organic materials from archaeological sites that are younger than 40,000 years, U-series techniques have been commonly applied

to carbonates, including shells, bones, and limestones (such as travertines). K-Ar dating is used at archaeological sites that can be stratigraphically linked to lava flows and tephras. The age range for dating using U-series is on the order of several hundred thousand years, while igneous materials that are millions of years old can be dated using the K-Ar technique. In recent years, newer techniques such as luminescence dating have become more reliable and are now being applied more often to understand the chronologic context of archaeological sites.

The concepts of paleontology are especially important in biostratigraphic correlation and taphonomy. These concepts have been applied in paleoethnobotanical studies and in palynology, and zooarchaeology. Their usefulness for geoarchaeologists is in relative dating (by biostratigraphic correlation), site formation, and providing information on environmental change as reflected by biotic communities. Research on environmental change connected with the archaeological record usually studies either the general habitat associated with human presence at a particular locality or the specific resources used by people (for instance, plants or animals that are incorporated into an archaeological site because of human activities). Palynology, the study of fossil pollen, has played a crucial role in documenting changes in climate and in human land use. Changes in the types and abundances of pollen over time generally reflect changes in vegetation. The changes in vegetation may be the result of climate change, such as changes in temperature or precipitation. For example, a drought would be reflected in a change in vegetation and could be related to a contemporaneous change in the archaeological record. As an alternative, the inferred changes in vegetation may reflect human land use, such as deforestation connected with agriculture. Macrobotanical remains have proven very useful for ethnobotanical studies and also are valuable materials for carbon 14 dating. Animal remains, including vertebrates and invertebrates, also provide information on the ancient environments and resources available for human use. Usually, invertebrate remains and fossils of small mammals provide useful information on local environments, while the fossils of larger mammals provide regional-scale environmental information. Biotic remains are also important in correlations between sites; these types of comparisons have been used to examine broader-scale environmental patterns or to help place a site within a time framework.

Climate and long-term environmental change are important topics in global archaeology, and geoarchaeologists play an important role in evaluating the interplay between human societies and natural systems. These studies have focused on the ways environmental change has impacted human biological and behavioral evolution as well as the ways humans have affected the environment. The techniques applied by geoarchaeologists to study the archaeological record and its context are especially valuable in documenting patterns of climate variation at different scales of space and time. Thus, geoarchaeological techniques are useful for understanding the record of human response to climate change at the scale of a single layer within a stratigraphic sequence at a site as well as evaluating patterns of human-environment interaction at regional, continental, and global scales.

Historical Background

The term geoarchaeology or its variations were rarely used in the scientific literature until the 1970s. The term is used to describe research that applies geoscience techniques to examine and evaluate the archaeological record. While the first explicitly geoarchaeological text might be considered Sir Charles Lyell's *Geological Evidence for the Antiquity of Man* published in the mid-nineteenth century, the history of using the geosciences to examine archaeological questions begins in the 1700s. Lyell likely would have called his work "archaeological geology," and this term is still in use today, for example, in the Archaeological Geology Division of the Geological Society of America (GSA).

One of the first and most important uses of geological concepts in archaeology is in stratigraphy. The use of stratigraphic principles to study

the archaeological record is based on ideas proposed by Niels Stensen (also known as Nicolaus Steno) in the 1660s and James Hutton in the late 1700s. John Frere's 1797 report of the discovery of stone hand axes within a stratified sedimentary sequence in England is a good early example of the application of stratigraphic principles to archaeological discoveries.

While the principles of stratigraphy were crucial to understanding the archaeological record, the emergence of ecological perspectives connected with past human-environment interactions also has a long history of application to archaeological studies. From 1799 to 1803, Alexander von Humboldt conducted pioneering field research on archaeological sites in South America and Mesoamerica. Characterized by an empirical approach, Humboldt included descriptions of the raw materials used in the archaeological monuments and, in one instance, documented the internal structure of the pyramid. His studies in Venezuela linked human activities such as deforestation and cultivation to environmental change. The *Principles of Geology* published by Lyell from 1830 to 1832 included descriptions of the geology associated with archaeological sites like Vesuvius, Pompeii, and Herculaneum. Like the earlier work of von Humboldt, Lyell also recognized the contribution of human activity to environmental change. Lyell writes about how deforestation since the time of Caesar during the Iron Age had transformed the landscapes of Europe. At the same time as Lyell's *Principles* was first published, Boucher de Perthes used the principles of stratigraphy to evaluate the association of artifacts and extinct animals in the terrace river gravels of the Somme Valley, France.

Geoscience techniques were also being used to study archaeological sites in North America. Squier and Davis published *Ancient Monuments of the Mississippi Valley* in 1848 using stratigraphic methods to evaluate whether human or geological processes had created mounds found in the Mississippi Valley. In 1855, Lapham published *The Antiquities of Wisconsin* demonstrating the ways archaeological information could be incorporated into studies of landscape evolution and connected with human activities. Lapham's studies provided an example of long-term changes in the landscape associated with the transformation from prehistoric hunting and gathering to agriculture and the construction of mounds. He concluded that land covered by forest at the time of European settlement had been cultivated during prehistoric times. This is a good historical example of a study that connected the study of present-day landforms to past human land use.

Archaeologists and geologists in Europe during the middle of the nineteenth century began to develop an understanding of the ways the record of the human past reflected the long-term patterns of human use of natural resources. A prominent example of this was the realization that there were changes in the types of raw materials used by people to create tools over time. Geologist Forchammer and archaeologist Worsaae conducted studies of shell middens in Denmark and Sweden and in 1848 collaborated with paleontologist Steerup. This multidisciplinary research became the basis for verifying the Three-Age System (Stone, Bronze, Iron) used in archaeology. Thus, in the mid-1800s, geoarchaeological techniques were being applied to both the contexts of artifacts (using stratigraphic principles) as well as the composition of artifacts to document sequences through time.

Another important historic application of geoscience techniques to archaeology was connected with the then controversial question of human antiquity. Excavations of Brixham Cave in England by Pengelly in 1858 provided well-documented evidence for the presence of humans with extinct Ice Age animals using systematic excavation techniques. The geoarchaeological observations undertaken by Pengelly, as well as Falconer, Prestwich, and Lyell eventually led to a breakthrough in our understanding of human antiquity. There were other influential publications during the 1860s. Lubbock published *Pre-Historic Times* in 1865 arguing that archaeology formed the bridge connecting geology and history.

Geoscience techniques were also an important part of classical archaeology during the last half of the 1800s, especially the use of stratigraphy. In

1860, Fiorelli started stratigraphic excavations at Pompeii, and in 1873, Conze used stratigraphic techniques during his excavations at Samothrace. In 1882, Dorpfeld began careful stratigraphic excavations at Hissarlik (Troy), following the earlier studies of Schliemann.

In America, Powell had one foot in geology and the other in ethnology; he helped establish the United States Geological Survey and the Bureau of American Ethnology in the late 1800s. There were many connections between the geosciences and archaeology during this time. Putnam worked for the survey and was known for careful archaeological excavations that employed arbitrary levels and documentation of stratigraphy. Powell felt that the evidence for a Paleolithic stage in North America had to be based on geological evidence. Likewise, Holmes, an energetic critic of the American Paleolithic, wrote that the only reliable test for human antiquity in North America rested on geology. During the 1890s, researchers such as Haynes, Abbott, and Salisbury believed the reliability of the geological evidence was crucial to evaluating archaeological sites. Winchell used his 1902 presidential address to the Geological Society of America to summarize the geological evidence for ancient humans in the New World.

During the early part of the 1900s, techniques from the geosciences were used to examine archaeological sites in the context of landscape change. Von Post used pollen studies to document vegetational change since the melting of the glaciers. Relative dating techniques were also employed. Varve dating was used by deGeer in Sweden, Sauramo in Finland, and Antevs in North America. Remote sensing in the form of aerial photography was also used. Crawford mapped over 200 archaeological sites in southern Britain using aerial photography as part of a study of settlement patterns and ancient landscapes. The links between environmental and climatic change and human activities were also of interest after 1900. In 1905, Pumpelly, another president of the Geological Society of America, applied geological methods to study the archaeology of the Anau in Turkestan.

In 1911, Gamio used a stratigraphic approach in excavations at Azcapotzalco in Mexico City, Mexico, and similar methods were employed in 1914 by Nelson at Pueblo San Cristobal. Beginning in 1915, Alfred Kidder used more controlled stratigraphic excavation techniques at Pecos Pueblo. Andersson, a Swedish economic geologist, pioneered geoarchaeology in China. He defined the Chinese Neolithic and excavated at the famous Paleolithic cave site at Zhoukoudian from 1921 to 1926.

By the 1920s and 1930s, Carl Sauer was developing his ideas about the landscape as a product of space, time, and natural and human processes. Sauer uses the term *archaeogeography* to designate the study of archaeological sites in relation to their environmental setting (Sauer and Brand 1932). From about 1924 to 1950, Kirk Bryan was the preeminent figure combining geoscience techniques and archaeology.

Bryan's student, Herbert Wright, served as geologist for excavations at Ksar Akil, Lebanon, and also participated with Robert Braidwood's multidisciplinary project in Kurdistan, northern Iraq.

During the 1950s, geological studies were part of many archaeological studies in the Old World and in the New World. In Old World studies, Judson conducted a study of the geological and geographical setting of Abri Pataud. Sedimentological studies of Abri Pataud were started by John Miller in 1958 and additional studies were completed by Bill Farrand in 1964. Karl Butzer began his geoarchaeological research in the Nile Valley of Egypt during 1956 and 1958. Cornwall's 1958 *Soils for the Archaeologist* demonstrated the great potential sediments and soils offered in archaeological analysis and interpretation. In New World studies, geology played a prominent role in Paleoindian research in western North America. For example, Evans conducted stratigraphic studies at the Clovis type-site in New Mexico and at Lubbock Lake, Texas. Wendorf led a team which included Albritton in the study of the Midland site in west Texas. C. Vance Haynes began his important geological studies of archaeological sites in the 1950s.

Pyddoke's 1961 *Stratification for the Archaeologist* emphasized the importance of stratigraphic context. One of the most important

contributions to geoarchaeology was Butzer's landmark *Environment and Archaeology* first published in 1964. In East Africa in 1962, Hay initiated his geological studies of Olduvai Gorge (Hay 1976). In Greece during the 1960s, William McDonald included earth scientists in a survey of Messenia, bringing in Wright (who had previously collaborated in archaeological projects in Lebanon and Iraq) then Rapp in 1966. Field studies conducted by Kraft, Aschenbrenner, and Rapp from 1971 to 1975 focused on the paleogeography of the coastal plain of the southwestern Peloponnese. The studies initiated by Kraft and Rapp in the 1970s turned into a long-term investigation of the ways coastal change has affected major archaeological sites in Greece and Turkey such as Troy, Ephesus, Ancient Pylos, and the landscape of the famous battle at Thermopylae.

Historically, events and publications during the 1970s and 1980s served to firmly establish the discipline of geoarchaeology. The enhanced visibility of geological applications to archaeology led to a short note coauthored by Rapp, Albritton, and Bullard entitled "Geoarchaeology Anyone?" in a 1974 newsletter of the Geological Society of America (GSA). The Archaeological Geology Division of the GSA was founded in the 1977, providing a venue and structure for specialists in the field. Several publications provided an understanding of the wide scope of geoscience techniques that could be applied to archaeological contexts and artifacts. For instance, in the late 1970s, an edited volume was published by Davidson and Shackley entitled *Geoarchaeology* and Vita-Finzi published *Archaeological Sites in Their Setting* (Butzer 1982). These were soon followed in the 1980s by Butzer's *Archaeology as Human Ecology* which emphasized the application of a geoarchaeological approach and *Archaeological Geology* edited by Rapp and Gifford which demonstrated the strong diversity of techniques used to understand the human past. The first volume of *Geoarchaeology: An International Journal* was published in 1986.

From the nineteenth century to the mid-twentieth century, the application of geology in archaeology was a "specialty" practiced by a few geologists. Since the last third of the twentieth century, it has become an organized discipline with professional societies, journals, conferences, and university programs. For the first 100 years or so, geoarchaeology was the province of the geologists. But since the late twentieth century, most geoarchaeologists have been educated in archaeology or anthropology departments and/or previously trained in geology, geography, and/or soil science. At the same time, some research traditions, especially those rooted in continental Europe, continue to emphasize the collaboration between archaeologists and earth scientists over and above the training of students as geoarchaeologists.

Key Issues/Current Debates

Because of the wide scope of geoarchaeology, it addresses many key questions regarding the long-term connections between humans and the environment. Indeed, there is a debate about how geoarchaeology is related to other disciplines that also study people and nature. For example, some people see geoarchaeology and archaeological geology as having the same goals, while others see them as using the same concepts but having different objectives. Although there does not seem to be too much controversy over the concepts and techniques, there are different perspectives on how these should be applied. For example, archaeological geology can be viewed as the use of the archaeological record to study geological questions in contrast to geoarchaeology which would apply geoscience techniques to answer archaeological questions. There is also a debate regarding the relationships between geoarchaeology and archaeometry. One approach is to place studies of sediments, soils, stratigraphy, and landforms within the realm of geoarchaeology and to distinguish it from archaeometry which would have a focus on geochronology, geophysics, and raw material analysis. Geoarchaeology has also been considered as a subdiscipline (along with zooarchaeology and archaeobotany) of environmental archaeology. Overall, geoarchaeology is a discipline that has as a primary goal the understanding of humans

and past environmental systems. Three keys issues that can be addressed using geoarchaeology are (1) human response to climate change, (2) human use of resources and impact on the environment, and (3) natural hazards and people.

Geoarchaeology is a critical source of information for examining human biological and behavioral responses to climate change. This includes biological adaptations to changes in climate as well as the response of ancient societies to climate change. Many questions connected with the ways humans use natural resources and impact the environment can be examined using geoarchaeology. Examples would include petrographic or geochemical provenance studies designed to study the flow of raw materials or studies of how resource exploitation is linked to erosion and sediment deposition and landscape evolution. Geoarchaeology thus can provide important information on the use and management/mismanagement of resources. Another focus of geoarchaeology is the use of records of the past to understand and predict environmental hazards. These include studying the patterns and effects of earthquakes and other geological catastrophes such as floods, volcanic eruptions, and tsunamis. A broad look at the dramatic effects of seismic events around the globe is given by Nur (2008). This volume covers major earthquakes from ancient Israel to modern Japan. A volume on archaeoseismology that details other seismic impacts is focused on the eastern Mediterranean, especially Greece (Stiros and Jones 1996).

International Perspectives and Future Directions

One of the important aspects of geoarchaeology is that it is an empirical natural science approach that can be applied to any archaeological record, regardless of its location on the globe. An emphasis on process and product encourages an international perspective. This is reflected in the *Developing International Geoarchaeology* (DIG) conferences which bring together a diversity of international researchers to share research and promote international studies in geoarchaeology. The application of geosciences techniques can be applied to any environmental context. Any region of the world can be studied using the geoarchaeological approach. For example, since the last third of the twentieth century, coastal studies in the Aegean and elsewhere have aided historians and archaeologists in discovering and understanding coastal sites. Kraft et al. (2007) provide an excellent example of how core drilling and the geological analyses of the sediment cores offer critical information about ancient Ephesus otherwise unavailable to archaeologists, historical geographers, and historians. On the other side of the world, Jing et al. (1995) show how sediment coring can discover deeply buried sites that would otherwise remain unknown, even after intensive surface survey. The geoarchaeological community has benefited from international cooperation and collaboration for both conducting field work and laboratory studies. Because geoarchaeology examines the way natural systems interact with humans, there is great value in the exchange of ideas and techniques that can be used to understand how ecosystems work at various scales of time and space.

Geoglyphs

Daniela Valenzuela[1] and Persis B. Clarkson[2]
[1]Universidad de Tarapacá, Arica, Chile
[2]Department of Anthropology, University of Winnipeg, Winnipeg, MB, Canada

Introduction

Geoglyphs are handmade features created on the surface of the earth. These have been made by removing or adding soil or stones. This creates

Geoglyphs, Fig. 1 The visibility of a linear geoglyph created using both additive and subtractive techniques is further enhanced by raking light that highlights differences in color and intensity between the geoglyph and the natural surface Nazca, Perú

contrast between the figure and the ground, enhancing visibility (Fig. 1). The most famous geoglyphs are in Nazca, Perú. Geoglyphs, nevertheless, also occur in a range of different forms worldwide. Despite the similarities that can be found between regions, it is clear that geoglyphs have independent origins and development in time and space.

Definition

What defines a geoglyph? This question is particularly relevant when we observe this phenomenon on a global scale; a wide variety of geoglyphs exist, although within limited parameters. Geoglyphs are intentional human made renderings of iconic/identifiable or non-iconic/unidentified forms placed over the surface of the earth, mainly by adding or removing material. Geoglyphs frequently include large-scale designs, i.e., either the individual figures are large or there are compositions of cluster of figures that extend over a sizable area. The term "geoglyph" may also apply to culturally significant patterns or locations resulting from ceremony, such as dance circles. A geoglyph's design – a llama, for example – fulfills a function which could be religious, aesthetic, economic, etc. Geoglyphs can last over time as a testament to activities or beliefs. Although we can identify its form, without additional information it is not possible to know its functions.

The term "geoglyph" was first used by the Venezuelan archaeologist Cruxent (1949), although it was Mostny (1964), head of the Anthropology section and subsequently the director of the Chilean Museo Nacional de Historia Natural, who explicitly defined this concept. Additional variants for the term include pintados, earth art, earthworks, terraforms, ground drawings, intaglios, mounds, stone arrangements, and ring ditches.

The creation of geoglyphs is accomplished through two techniques, additive and subtractive, either singly or in combination (Fig. 1). Making a geoglyph does not require a great deal of labor investment. Generally, the materials are not large or heavy, and the activity is not labor intensive, and thus, the task can be undertaken by the very young through to the very old. Some techniques require a greater degree of labor investment, such as the geoglyphs from Venezuela and Colombia, where the figures are engraved on rocky slopes, or the Amazonian mounds constructed within minimally cleared areas in forests, and the excavation of deep trenches to supply the sufficient quantities of heaped earth for platforms (Watling et al. 2017).

The specific location, size, style, and situation of geoglyphs on the ground have direct implications for their visibility. Geoglyphs on slopes are visible from a distance (Fig. 2). Geoglyphs situated on flat or horizontal surfaces are more difficult to see from a distance, although they can be discernible up close, or "seen" through the senses when people walk or move over the geoglyph (Fig. 3). Large geoglyphs (e.g., Nazca) and three-dimensional (e.g., Hopewell/Adena, Amazonia) geoglyphs may be difficult to discern in their totality. The

Geoglyphs, Fig. 2 Traditional llama caravan passes below additive/subtractive geoglyphs inscribed high on hillsides at Cerros Pintados, Chile, which are visible from both near and far

Geoglyphs, Fig. 3 Linear trapezoidal geoglyph Nazca, Perú

use or significance of some geoglyphs can be understood from oral traditions and indigenous knowledge. Thus, geoglyphs are comprehended visually (e.g., in Chile, England, Venezuela, and Colombia) or experienced (e.g., Nazca) or known (e.g., Californian rituals).

The relationship between the suitability of the earth's surface and the visibility of geoglyphs results in different kinds of techniques employed by the geoglyph makers. Suitable natural surfaces are common in arid regions of western Americas (e.g., Nazca in Perú, northern Chile, western US states, and Mexico), Argentina, Australia, Algeria, Libya, Egypt, Israel, and Kazakhstan. In such regions, images are added to or created on the natural surface. Forested or otherwise verdant landscapes required clearing prior to creating geoglyphs. These areas include the effigy mounds

Geoglyphs, Fig. 4 Additive geoglyph composition of camelids situated on a gentle slope is comprised of large stones. Quebrada de Tiliviche, Chile: (**a**) view of the geoglyphs location on the slope of the river, (**b**) aerial view of geoglyphs associated to caravan trails, and (**c**) detail of the figures made by additive technique. of the Mississippi Basin (Hopewell and Adena cultures) and the Amazon Basin.

The construction technique and placement can also affect durability as well as the visibility of geoglyphs. Images on slopes, such as the Uffington Horse in England, are visible from a long distance. The use of large stones to form a large panel of numerous figures on a moderately sloped surface at Quebrada Tiliviche in northern Chile has withstood the effects of gravity, wind, and rain (Fig. 4). Geoglyphs created with heaped soft soils or on steep slopes are less likely to withstand the effects of these natural processes. Visibility of geoglyphs is enhanced by raking light; this is particularly evident in older geoglyphs where the color or texture contrast between the original surface and disturbed subsurface may fade over time.

Key Issues

Purposes

Geoglyphs belong to a class of material culture commonly described as having religious, ritual, or ceremonial functions, when and if no utilitarian function is clearly evident (Clarkson 1998). In fact, in virtually every region where geoglyphs can be found, the main purpose in the construction of a geoglyph has been attributed to ceremonial and ritual activities. There are, obviously, other valid interpretations of ethnographic evidence of ritual or ceremonial use. References to shamanic activities associated with geoglyphs in pre-European contexts have been framed in cognitive archaeological explanations that employ scientific methodologies within social science and humanities investigations (Lewis-Williams 2010).

In the Bolivian Altiplano, it is thought that the so-called Sajama lines were originally associated with sacred places and mountain worship. This interpretation has been backed by ethnographic documentation (Morrison 1978; Reinhard 1996). The enigmatic geoglyphs of the Mojave Desert, in the southwestern United States, were interpreted as "rites of passage" in the nineteenth and twentieth centuries through ethnographic accounts and ceremonies (Johnson 1985). In Nazca, Perú, a variety of reasons have been suggested: geoglyphs had astronomical purposes limited evidence and served as pilgrimage sites, as well as place to worship ancestors, mountains, water, and fertility, among other functions. Cosmological and astronomical functions have been proposed for Mound 72 and other mounds at Cahokia

(Illinois, USA), a major site of the Mississippian culture, dated between 800 and 1350 CE. There are also rich ethnohistorical sources dating to the seventeenth century and later on Mississippian culture, including cosmological rituals and activities (Demel and Hall 1998). The geoglyphs of northern Chile are one of the few cases that seem also to have included a utilitarian purpose: they served as logistical markers to indicate routes for llama caravans on the western slope of the Andes. Similarly, the colored stone structures found in the province of La Rioja, Argentina, associated with water sources and natural steps, could have been related to trading routes of pre-Hispanic populations (Callegari and Raviña 2000).

Some geoglyphs executed on horizontal surfaces, particularly large images, are visually best observed from a distant or elevated location directly from above (Fig. 5). Aerial visual conceptualizations popularly invoke an intention for deities, supernaturals, or humans in altered states of consciousness. San Pedro cactus (*Trichocereus pachanoi*), portrayed on Nazca ceramics and native to the Nazca and Andean regions, contains hallucinogenic alkaloids which can produce a sensation of flying. Ethnographic evidence from southern California indicates that walking on and/or tracing the outline of geoglyphs was intended or practiced (Johnson 1985). Nazca figural geoglyphs were consistently made with a single line that scribes the entire figure, regardless of the complexity. The width of the line is consistent with that of a footpath, and thus, an individual can (de)scribe an entire figure, beginning and ending at the same location. The sensual and ritual effect is analogous to walking a prescribed route, such as the effect attributed to the thirteenth-century labyrinth in the floor of Chartres Cathedral, where the meandering line of the labyrinth is said to have been intended to be experienced as a ritual of devotion and contemplation or as a simulation of pilgrimage to the Holy Land. Similarly, the "wheel" and "pendant" forms reported in Arabia may have been used for the ritual circumambulation of sacred spaces, identified in both Islamic and early Arabic contexts (Kennedy 2011).

Distribution

Geoglyphs are known from every continent, except Antarctica (Fig. 6).

North America

In North America, the earliest geoglyphs described in the literature were the earthen mounds found throughout the Mississippi River and Ohio River basins and around the Great Lakes. The effigy mounds are naturalistic renderings of identifiable fauna, often in clusters. The complexity and precision of execution of both

Geoglyphs, Fig. 5 A large geoglyph of a spider inscribed on a horizontal surface is difficult to discern from a static location on the ground; the entire figure is visible from the air (approximate length 45 m/150 ft)

Geoglyphs, Fig. 6 Locations of geoglyphs discussed in the text

G

effigy and geometric mounds belie large-scale effort and abstract visual comprehension of images that could only be viewed from above or by walking around and over them. The makers of these mounds are collectively referred to as "mound builders," and the mounds span broad cultural and temporal spheres, dating as early as approximately BCE 3500 (e.g., Watson Brake in Louisiana) and continuing up to European presence in the sixteenth century. The "mound builders" were alternately ascribed to Phoenicians, Egyptians, Romans, lost tribes of Israel, etc., in line with pre-twentieth-century "scholarly" thinking that ignored both the long-term presence of indigenous populations and their successful, unique, varied, and complex adaptations in the New World.

Subsequent explorations throughout the Americas have revealed additional examples of geoglyphs in the arid western regions of North and South America. These geoglyphs use the landscape as a natural "blackboard" on which soil and stone were scraped or heaped up to form low-profile naturalistic or abstract images, as well as alignments of stones or boulders. Cultural assignation of geoglyphs in the western regions of North America is difficult to ascertain due to a general lack of associated and dateable sites, material culture, or ethnographic reference. Some geoglyphs in the Great Basin and West may date to the Paleo-Indian (at least 13,000 years ago) or Archaic (BCE 8000-2000, up to the nineteenth century in some areas) periods. Research on geoglyphs in the American Southwest and the Northern Plains of the United States and Canada has revealed viable hypotheses regarding historic or protohistoric cultural affiliation of use, age, and purposes of the geoglyphs (Whitley 2000; Aveni 2008). The forms of these geoglyphs are varied and reflect a diverse cultural and chronological history. "Medicine wheels" on the Northern Plains have been correlated with astronomical or cosmological significance (Aveni 2008), while geoglyphs in the Southwest (California and Arizona, USA) and adjacent regions of Sonora (Mexico) have been ethnographically correlated with historic Akimel O'odham (Pima) and Tohono O'odham (Papago) peoples relating to their dance circles, community rituals, and social identifiers. The geoglyphs in these regions, known also in the literature as "alignments," "gravel effigies," and "pictographs," have proven difficult to date due to the general lack of chronological markers within or associated with the geoglyphs (Whitley 2000) (Fig. 7).

Geoglyphs, Fig. 7 Subtractive geoglyph of indeterminate age, cultural affiliation, or representation in the Colorado River region. (Photo permission of R. Dorn)

Researchers also extend the term "geoglyph" to refer to other culturally significant patterns or locations resulting from rituals associated with puberty rites, healing, harvest feasts, and origin myths, particularly in the American Southwest. The information is derived from natives living in and historically associated with the areas where such geoglyphs occur (Johnson 1985). The categories that distinguish these so-called patterns from geoglyphs are often indistinguishable to the Western researcher. The patterns convey information to the traditional people of the region, a unique form of art. Comparisons have also been drawn to the similarity of subject matter, motif, and execution technique between geoglyphs and petroglyphs (Davis and Winslow 1965) and sand paintings, although there is no evidence that people who created geoglyphs also created sand paintings (Harner 1953; Cohen 1987). Petroglyphs are also known as rock art, and sand paintings are elaborate images of mythological beings created during healing ceremonies and subsequently destroyed as part of the cure. Among the Navaho, the mastery of sand painting is deeply embedded with the intensive training for healers. Thus, ethnographically documented purposes for the artistic expressions of geoglyphs are usefully applied as hypothetical analogies elsewhere.

South America

The coastal deserts of western South America comprise excellent conditions for the creation of geoglyphs – minimal vegetation, minimally dissected terrain, and soils and stone suitable for creation. In Perú, the most famous geoglyphs are those in the region of Nazca, but geoglyphs have been found from the north coast to the southern tip of this country (see the entry on "Nasca and Pampa Jumana Lines and Geoglyphs" in this encyclopedia). Apart from the Nazca region, geoglyphs can also be found in the north coast valleys of Santa, Jequetepeque, and Moche, Rimac and Casma on the central coast, and in the valleys of Majes, Sihuas, Moquegua, and Tacna in the south coast (see Wilson 1988; Abanto 2009; Bikoulis et al. 2016). The geoglyphs in Perú have been made by using both extractive and additive techniques. In Nazca, most linear and biomorphic geoglyphs are made through an extractive technique, while the additive technique is limited to certain biomorphs from the Andean highlands (see the entry on "Nasca and Pampa Jumana Lines and Geoglyphs" in this encyclopedia). In the north, central, and south parts of the country, geoglyphs have been created using both additive and extractive techniques, and their forms vary from geometric to figurative.

In northern Chile, geoglyphs were first noted by European travelers and geographers during the eighteenth and nineteenth century. They are found mainly in lowland valleys and are scattered in the slopes and plains of the western side of the Andes and the coast. They can be also found in the Arica, Tarapacá, and Antofagasta regions. Here, geoglyphs show significant differences in terms of technique: additive, subtractive, and mixed, displaying an array of regional style, culture, and traditions (Briones 2006). The majority of the motifs are zoomorphic, mainly camelids, and there are also a variety of anthropomorphs (often with camelids) and geometric motifs. In general, geoglyphs in northern Chile are located on slopes, but they can also be found on horizontal surfaces, all of them normally associated with caravan trails (Figs. 4 and 8). This consistent association has led to geoglyphs being interpreted in terms of their functional and symbolic relationships to the caravan system and routes that connected the Andes and the Pacific coast during pre-European times (Núñez 1976; Pimentel 2011). Although most geoglyphs currently are dated from the late pre-Hispanic period (c. CE 900–1535), it is thought geoglyphs began to be used from the Late Formative period (c. BCE 500 - CE 600), as evidenced by funerary manifestations directly associated with them (Briones 2006).

Geoglyphs are also located in the highlands of South America. In Chile, geoglyphs can be found in the Zapahuira region in the Sierra de Arica (Briones 2006). The highland Bolivian Sajama region in the province of Oruro is home to several hundred-plus linear geoglyphs spread across a wide area of the Andean uplands. The "Sajama lines" were documented over a century ago by a variety of anthropologists and explorers (Morrison 1978). Their age and purpose remain

Geoglyphs, Fig. 8 A principal north to south caravan trail cuts across the Quebrada de los Pintados (Chile), flanked by geoglyphs on both sloped and horizontal surfaces. Geoglyphs on slopes are visible from the ground (**a**) and aerial views of both sloped (**b**) is an aerial view of (**a**) and horizontal surfaces easier to conceptualize. The different styles and themes of the geoglyphs may indicate different cultural and/or chronological factors

enigmatic, although parallels have been drawn to the appearance of Nazca line centers, ancient and modern Andean traditions related to ritual travel, and the Inca ceque system. Many of the Sajama lines coincide with community boundaries, and lines often extend between communities and major peaks (Tierra Sajama n.d.).

In Argentina, geoglyphs with particular technical and stylistic features have been discovered in recent archaeological explorations. They are located mainly in La Rioja province, although isolated examples can be found in Salta, San Juan, San Luis, and Mendoza. So far, all known geoglyphs in Argentina were made with an additive technique by heaping rocks and dirt on horizontal surfaces. Noteworthy are tall structures or structures of tamped earth covered with black, white, and red colored stones that were deliberately selected to form geometric shapes like circles and stars; the structures range in size from approximately 10–30 m (Callegari and Raviña 2000). Some of the geoglyphs are associated with sites of the Aguada culture (550–900 CE), although the chronology is still uncertain (Fig. 9).

There have been recent isolated reports of geoglyphs in areas where they were previously unknown, such as in the high valleys of the western state of Carabobo, north-central Venezuela (Urbani and Urbani 2001). The technique used in this region to create geoglyphs is unique: these occur as large circular and linear shapes

Geoglyphs, Fig. 9 Additive geoglyph of colored stones in Piedras de Afilar, Ischigualasto, San Juan, Argentina. (Photo permission of Mercedes Podestá and M. Pía Falchi)

(c. 35 × 42 m) and are located on rocky slopes. They are made by an engraving percussion technique (Urbani and Urbani 2001). Given their large size and location on the hillsides, these petroglyphs have been termed geoglyphs.

Geoglyphs were first identified in the Amazon region of Brazil and Bolivia in the late twentieth century, and only recently have they been conceptualized and recognized as geoglyphs. There are two main areas of distribution: the Baure region in the Bolivian Amazon and the Acre region in the Brazilian Amazon (Pärssinen et al. 2009; Erickson 2010; Bikoulis et al. 2016). These are large structures built by digging a deep trench and heaping the removed soil into desired forms. Their shapes are largely geometric circles and ellipses; octagonal, hexagonal, square, rectangular, "U", groups of circles, and concentric circles have also been observed. The perfect geometric forms suggest a symbolic significance (Pärssinen et al. 2009: 1093–1094). A variety of other functions, such as defense, settlements, residences of the elite, land and resource markers, animal traps, cemeteries, transportation routes water management features, and/or ceremonial public spaces, have also been proposed (Erickson 2010).

Australia

Numerous examples of geoglyphs referred to as "stone arrangements" have been documented in Australia. "Stone arrangement" is a broad category that includes features consistent with those shared with geoglyphs. These earth features characteristically appear in arid coastal regions of central, western, and northern Australia. Usually the geoglyphs take geometric, circular, and linear forms, as well as those of figurative effigies of animals. They are made by laying stones on horizontal surfaces on the ground or, in some cases, in intertidal zones along the coast. The meanings of some of these features have been discerned through rich ethnographic and ethnohistorical data, plus recent archaeological research. These geoglyphs were integral to traditional Aboriginal ceremonies, marking totemic centers or locations associated with myth, in addition to places where initiation ceremony and rites of passage occurred, among others (Mathews 1896; McNiven 2003; David et al. 2004).

Africa and Asia

In Algeria, Libya, and Egypt, geometric shapes, such as irregular and meandering lines, created by clearing dirt and rocks, are located on horizontal

desert surfaces (Gauthier 2007). In Israel, geoglyphs have been described in the Negev Desert, made by extractive and additive techniques (Anati 1999). The distribution, forms, meanings, functions, and timing of these geoglyphs are unknown.

An extensive remote sensing study in Arabia (including Syria, Jordan, Egypt, Israel, Saudi Arabia, and Yemen) has revealed hundreds of thousands of "structures" that are analogous to geoglyphs. Referred to as "works of the Old Men" by Bedouin from a number of regions in Arabia, these forms can extend up to several kilometers. The purposes ascribed to the variety of forms include hunting traps, funerary sites, ritual feasting, and possible astronomical or directional alignments. Chronological assessments via relative dating indicate these are up to 9000 years old (Kennedy 2011).

The discovery of up to several hundred geoglyphs in Kazakhstan has extended suggestion that a long-held anthropological theory that monumental art and constructions were coincident with settled life is too simplistic and that the lifeways of nomadic peoples were more complex than generally attributed (Blumenthal 2015). OSL dating and archaeological fieldwork in the region of the geoglyphs suggest a maximum age of 800 B.C. (Jarus 2015; Logvin et al. 2014).

Europe

The Uffington White Horse (Oxfordshire) is the best reliably confirmed geoglyph in England (Pollard 2017). The 2000-year-old Bronze Age figure was constructed by digging a trench and filling it with chunks of locally available white chalk. Other chalk figures are known in England, although their authenticity as ancient monuments is discredited in many cases.

Chronology

Two methods have been used to date geoglyphs: relative dating and absolute dating. Relative dating relies on associating artifacts of known age with the geoglyphs. It is usually difficult to determine what the association is between the stone features and artifacts found nearby. Furthermore, geoglyphs were likely reused, and therefore, the associated artifacts could relate to the construction event or subsequent use of the geoglyphs. For example, in northern Chile, geoglyphs associated with caravan trails and habitation sites between the oasis of Tamentica and the Quebrada de los Pintados were likely reused, reinterpreted, and redrawn over a considerable time period. The reuse of geoglyphs is indicated by superimposed drawings, although it is difficult to determine the chronological interval: it could be 1 hour or a millennium. When superimposed drawings have distinct stylistic/iconographic features, reuse over time can be suggested. Relative dates also can be established through stylistic and iconographic comparisons with dated iconography, such as that found on ceramics, textiles, baskets, or gourds, thus providing viable ages (Kennedy 2011). Lastly, patination may indicate relative ages within the same ecological zone (Dorn 2009). Absolute dates are provided by a variety of different chronometric analyses, such as cation ratio, 14 C, AMS 14 C, pedogenic-carbonate inversion (PCI), varnish microlamination stratigraphy (VML), 36 Cl, backscattered electron microscopy (BSE), and energy dispersive X-ray analysis (EDS), with the appropriate technique applied in different environments and contexts (Dalton 1999; Dorn 2009).

Future Directions

The fragile and ephemeral nature of geoglyphs has led to an increase in recent years in national and international efforts to conserve, preserve, protect, and document geoglyphs. Geoglyphs situated in undeveloped regions had been shielded from all except natural factors (e.g., erosion and taphonomy). In other regions, geoglyphs have disappeared in the wake of agricultural expansion, residential and urban construction, resource exploration and exploitation, through recreational activities, particularly those involving motorized vehicles, and armed conflict (Fig. 10).

Some circumstances make the protection and conservation of geoglyphs an arduous task: remote locations are difficult to police and protect, and funding is limited. In the north of Chile, a

Geoglyphs, Fig. 10 Geoglyphs inscribed on the slopes of Cerro Caramucho (Chile) were irreparably damaged by recreational vehicles sometime between 1998 and 2000. The area was signed as an archaeological site

process of documentation, restoration, and conservation of geoglyphs was carried out during the 1970s and 1980s, supported by the government and the University of Tarapacá. One example of effective management is the case of Cerros Pintados (northern Chile), where vehicle access is controlled, and there are designated footpaths, guards, and an entrance fee. Similarly, in Nazca (Perú), guards are stationed at key locations, and aerial flights over the geoglyphs are encouraged and popular. Nevertheless, illegal incidents of modern creation of geoglyphs within archaeologically protected zones in Perú and Chile have been documented, usually after irreparable damage has been done. Some of these modern creations have made their way into the literature as examples of the ancient corpus, in spite of documentation to the contrary.

The well-known "trident" geoglyph prominently inscribed on the slope facing the Paracas Bay in Perú has been documented as a creation of late Colonial times but continues to be featured in the corpus of "ancient" geoglyphs in the Nazca tradition. Unfortunately, dangerous remote locations cannot feasibly be studied or protected (e.g., northern Mexico is currently a domain of drug cartels, *coyotes* etc.; see Hayden 1998), and sites situated on either side of the US-Mexico border are difficult to coordinate under a single research program.

The advent of new technologies, beginning with aerial photography early in the twentieth century, has led to discovery in regions that are otherwise poor in natural resources or difficult to access: the enormous repertoire of geoglyphs in Arabia is an excellent case in point (Kennedy 2011). Subsequent refinements to remote sensing, such as satellite imagery, infrared and SLR ("side-looking radar") for vegetated areas, and easy access to Google Earth, have increased the inventory of geoglyphs. The ready access to information for scientific research on the geoglyphs is accompanied by increased likelihood of damage as a result of recreation and

economic exploration that needs to be addressed by local governments before it is too late.

Geometric Earthworks of Western Amazonia

Denise Schaan
Programa de Pós-Graduação em Antropologia, Universidade Federal do Pará. PPGA, Belem, PA, Brazil

State of Knowledge and Current Debates

The geometric earthworks of Western Amazonia are huge ditched and walled enclosures built by pre-Columbian peoples from 1200 BCE to the seventeenth century. They are found over an enormous area that stretches over 490 miles in the west-east direction and about 400 miles in the south-north direction, in the Brazilian States of Acre (Eastern half), Rondônia, and Amazonas (South), as well as in Northern Bolivia (Fig. 1). The enclosures are in average the size of a city block but might measure up to four football fields. The regularity of the measurements and shapes has impressed scientists the most; many are perfect squares, circles, and hexagons but also composite figures (Fig. 2). The fact that they are better appreciated from airplanes makes people think they were made for a superior being to watch them. But who made them? With what purpose? What kinds of tools were used for building such gigantic structures in areas of dense forest? Over the past 10 years, teams of scientists from Brazil, Bolivia, Finland, the United States, England, and Germany have tried to answer these and other questions. This chapter brings the state of art and current debates regarding the geometric earthworks of the Amazon River basin.

The History of Discovery

In 1963, an article in *American Antiquity* featured aerial observations by the geologist George Plafker on what he called "remnants of cultivated fields, causeways, and canals" in Northeastern Bolivia, which he interpreted as "evidences of an extensive ancient civilization" (Plafker 1963: 372). In the

G

Geometric Earthworks of Western Amazonia, Fig. 1 Location of geometric earthworks in Western Amazonia. By Antonia D. Barbosa

same year, in the following number of the same journal, William Denevan, a cultural geographer, published a detailed account of the earthworks mentioned previously by Plafker. The numbers were impressive: in a 250 square mile area in the Llanos de Mojos, he counted 20,000 drained fields, 1000 miles of causeways, 42 over 10 feet high mounds, and "a large number of circular ditches (zanjas)." Denevan (1963: 542) concluded that the "ditches probably surrounded villages or shifting farms and had some sort of defensive purpose."

At that time, earthworks had already been recognized in other parts of the lowlands, but environmental determinism in archaeology was so strong that they were treated as exceptions. Meggers' 1954 article, "Environmental limitations to the development of culture," followed by her 1957 monograph on Marajo Island and her 1971 best seller *Men and Culture in a Counterfeit Paradise* had convinced archaeologists and the public opinion that the tropical environment placed serious limitations to food production and population growth. Reasons were the poor soils, cyclical climatic stresses (El Niño Southern Oscillation – ENSO), and shortage of protein (available mostly from hunting and seasonal fishing). Meggers and Steward (1950), her mentor, looked for evidence in the ethnography of living Amazonian natives, who they described as riverine peoples, living on manioc and game, at the edge of starvation, incapable of developing chiefdoms (as in Central America) or states (such as the Inca). They do not consider, however, that the so-called tropical forest peoples had their cultures and ways of life dramatically impacted by four centuries of colonization and decimation through diseases and war. So, whenever they saw evidence for complex societies, they characterized them as exterior to the basin. And although their views were strongly criticized from their inception, it

Geometric Earthworks of Western Amazonia, Fig. 2 Geometric earthworks in the state of Acre, Brazil. (**a**) – Site Fazenda Atlantica (Photo: Sergio Valle); (**b**) – site Gavião (Photo: Edison Caetano); (**c**) – site JK (Photo: Diego Gurgel); (**d**) – site Tequinho (Photo: Diego Gurgel)

took over 30 years to overcome them in Amazonian archaeology.

In Brazil, the geometric earthworks were first seen from the ground, in 1977, when a Brazilian archaeologist, Ondemar Dias, found circular ditches with exterior embankments in Acre, while surveying for a national archaeological program in Brazil partially sponsored by the Smithsonian Institution and directed by Betty Meggers (Dias 2008). At that time in Brazil large portions of the territory were unknown archaeologically, and Amazonia was considered a land where societies had lived for centuries without disturbing much of the ecosystems. Archaeologists were most interested in finding pottery sherds and classifying them into phases and traditions. So, although Ondemar Dias found eight sites with circular enclosures, he preferred to give more importance to the ceramics he collected for classification into archaeological phases. Eleven years later, the paleontologist and geographer Alceu Ranzi would become the first to see a geometric structure from the air in Brazil, aboard a flight from Porto Velho (Rondônia) to Rio Branco (Acre). Another decade will pass and Ranzi, again, spotted another structure from the air. The trained geographer knew these were not natural formations and started to record them, using small airplanes. In 2000 he had already counted 24 sites; relating them to the Nazca Lines, he named them "geoglyphs," a name that has since gained popularity in Brazil (Ranzi 2003).

While in Brazil, research on earthworks was limited until the inception of the twenty-first century; given the dominance of environmental determinism, in Bolivia, during the three or four decades that followed that initial survey, it was the raised fields that deserved most of the scholars' attention. So, although the existence of ditched enclosures was acknowledged over 40 years ago, it was not before the beginning of this century that they would be studied, both in

Bolivia and Brazil. This delay has several reasons besides the ones outlined above. First, there was a shortage of archaeologists working in the Amazon basin, given the difficulties with logistics and lack of adequate training. Second, the most important tool used to search earthworks remotely would be available much later: Google Earth free satellite imagery. Third, deforestation was not as critical as to uncover too many structures as it would be later.

The research started almost simultaneously in Brazil and Bolivia. In Brazil, a Brazilian-Finish team led by Denise Schaan and Martti Pärssinen began cooperation in 2005, being responsible, over the years, for several projects that included extensive surveys and excavations. In Bolivia, Clark Erickson, who, as Denevan student, had for most of his career focused on the raised fields research, in 2007 carries an extensive survey on the circular ditches (which they called zanjas circundantes), together with two Bolivian colleagues, Patrícia Álvarez and Sergio Calla (Erickson et al. 2008).

The amount of sites found in a couple of years of regional surveys amazed everyone. Soon it became clear that the Amazon forest had rapidly regenerated over hundreds of earthworks, and scholars began to think this was only the tip of the iceberg. Besides satellite imagery, aerial photography has been used to identify sites and the structures with more precision than pedestrian surveys. This is because given to erosion, many sites are poorly recognized from the ground level. So, while satellite image allows for the recognition of ditches, photos taken from small airplanes in the first morning hours delineates well "positive" structures, e.g., embankments, mounds, and walled roads, that make up the sites as a complex of earthwork features (Fig. 2).

At first, ditched enclosures in Acre were interpreted as remnants of ancient village sites, perhaps organized in regional level, following the same reasoning for other complex societies in the Amazon basin such as the ethnohistorical Tapajós or the mound builders of Marajo Island. In Acre, however, it appeared that complex societies had flourished also in *terra firme* (upland, areas not subjected to seasonal flooding) environments, adding to the Xingu data, where large societies had built "garden cities" beginning in 1000 AD (Heckenberger et al. 2013). As excavations progressed, however, a different picture began to emerge. First, the geometric enclosures lacked cultural remains of large sedentary populations, if compared to hundreds of archaeological sites, from the upper to the lower Amazon River. Sites would have only scattered ceramic sherds, soil chemistry showed no traces of large amounts of human waste, and the ubiquitous terra preta (Amazonian Dark Earths, ADE) was also absent. Besides, the earthmovers of Acre, radiocarbon dates showed, are much older than other complex societies in the basin. More than 20 calibrated radiocarbon dates place them in the first millennium ACE, although there are dates that show the beginning of earthmoving activities around 1200 BCE and the end by 1400 ACE. Now, scholars have proposed that the geometric enclosures in Brazil were built by highly mobile populations, as places for meetings, ceremonies, and rituals of peoples who would gather there over time, in certain periods of the year (Saunaluoma and Schaan 2012). These constructions would not be tied to particular ethnic groups but would be part of a shared technique and cosmology of societies in their formative state.

Other scholars, such as paleoecologist Francis Mayle, the palynologists Jose Iriarte and Jennifer Watling, and other students have joined the archaeologists working both in Bolivia and Brazil. They have helped to answer questions related to food production and the environmental scenario at the time of earthwork construction. Also, over the years, geologists, historians, anthropologists, soils scientists, and botanists have also looked for answers. In the remaining of this chapter the reader will find out what is known and what we still don't know about the geometric earthworks in Brazil and Bolivia. The data is organized by regions, taken in account similarities and differences between the landscapes and sites.

Earthwork Sites in Acre and Amazonas States in Brazil

Here the earthworks occur between the upper tributaries of the Purus River (Iaco and Acre

River) and the Madeira River (Abunã River). The earthworks were built on the plateau edges that top the valleys between129 and 285 masl. The placement of the earthworks in the highest spot in the landscape speaks of its ritual significance, as well as a defensive strategy, since from up there one could see whoever would approach coming from the rivers, several miles away. However, as one approaches the mouth of the Acre River at the Purus, in the state of Amazonas, there are earthworks in the lowland varzea (seasonally flooded areas) but not close to the main river.

There are 459 earthwork sites in Acre that sum up 600 ditched or walled enclosures. In the state of Amazonas there are 145 earthwork sites, with about 170 ditched enclosures (Fig. 3). An earthwork site might have only one enclosure, or up to six enclosures, linear embankments, mounds, associated roads, and other structures. The proximity of earthworks characterizes a site. About 80% of the sites are comprised by only one ditched enclosure, either a circle or a square. Circles are more common in the south, and squares are more common in the north (Fig. 4). Only 2% of the sites have shapes that differ from circles or squares, which occur in similar number in Acre. In Amazonas, squares are more common than circles.

There is still another type of site, associated with geoglyphs. These are clearly village sites formed by little mounds placed around a circular, open area. There are nine mound sites known to Acre only (Fig. 5). Excavations at these sites have yielded few cultural materials, mostly ceramics. The difference is that ceramics tend to be more elaborated; there are spindle whorls and polychrome wares. These sites were partially contemporaneous with the ditched enclosures, but in a later period.

About 30% of the sites are associated to roads of various lengths (up to 1 km), either connecting two enclosures or pointing to the main rivers. Roads are typically sunken paths with lineal embankments on both sides, since the earth was

Geometric Earthworks of Western Amazonia, Fig. 4 Distribution of earthworks in relation to shape. By Antonia D. Barbosa

piled in the outside, and are about 18 m large. They have most likely been cleaned of vegetation periodically, and dug to the clay soil, which explains why they are so visible in the landscape so many centuries and even millennia after abandonment.

Excavations of 15 sites in Acre have helped scholars to build a comprehensive chronology and begin to understand site function. In some sites, it is possible to observe different episodes of construction, which indicates that, in different moments in time, the earthworks were rebuilt and that new structures were raised over the old ones. Different from other Amazonian sites that have abundant pottery sherds in black soil (ADE), here ceramics are scanty, their amounts vary a lot among sites, and anthropogenic soils are absent. In general ceramics are found in the embankments and inside the ditches, to where it was carried probably because of erosion. So, it seems that part of the ceramics was incorporated to the enclosures during its construction, while others were discarded as a result of breakage during its use. Although ceramics vary among sites, from poorly mixed and low-fired vessels to more elaborate, polychrome wares, there is one type of incised pottery that is recurrent and resembles styles of the Ucayali River, upper Amazon sites. Saunaluoma (2012) found a fragmented entire vessel belonging to this style (Fig. 6-I) as part of a votive offering in the Fazenda Atlântica site, together with animal bones, ashes, and calcium carbonate, a chemical compound known to be used in conjunction with coca leaves. In this and other sites, chunks of clay with stick impressions have been interpreted as remnants of adobe houses, or at least doorways or small huts built nearby the enclosures main entrance.

Excavations of the ditches have revealed interesting features, such as negatives of clapboard

Geometric Earthworks of Western Amazonia, Fig. 5 Mound village sites in the state of Acre, Brazil. (**a**) – Site Fazenda Iquiri II (Photo: Diego Gurgel); (**b**) – Montículos Plácido (Photo: Diego Gurgel); (**c**) – Fonte Boa (Photo: Edison Caetano); (**d**) – Sol do Iquiri (Photo: Diego Gurgel)

placed at its bottom, with the purpose of preventing the straight walls to fall off. The ditches, as one might expect, were much more profound and also steeper in the past (Fig. 7). Erosion has carried at least 2 m of sediment to the ditches and has flattened external embankments that would be much higher at the time they were in use.

Paleoecological and palynological research conducted in Acre have given clues on what the ditch builders ate and what the landscape looked like at the time of the construction. Pollen samples were collected in nearby lakes, and phytolith samples were obtained in test pit dug along transects in and out sites and in controlled excavations in selected sites. Phytoliths of the cob of domesticated maize and squash were found in both archaeological contexts and in residues of artifacts in four sites in Acre (Watling et al. 2015). More abundant than these two domesticates, however, were phytoliths of non-domesticated palms, which we know are used by Amazonian peoples for a variety of reasons, from food to utensils and houses. The study of Watling and colleague concluded that squash and maize were grown in Acre at least from the beginning of the common era, where they planted and managed both domesticated and wild resources. The human management of the landscape during at least the last 6000 years has created an anthropogenic forest, dominated by palms and bamboos, which explains why it was not too hard to build the gigantic structures. They took advantage of this partially opened, easy to clear forest, which has remained with the same species dominance until nowadays (Watling et al. 2017).

Scholars today agree that the earthworks of Acre and Amazonas states were built by a population in the formative stage, which was not yet fully sedentary (Saunaluoma and Schaan 2012). The enclosures were gathering places, places for festivities and rituals. Their sizes and shapes would have made humans to feel small and

Geometric Earthworks of Western Amazonia, Fig. 6 Material culture associated with geometric earthworks. (**a**, **b** y **c**) – Vessel and sherds from site Tequinho, Acre; (**d**, **e** y **f**) – spindle whorls from site Tequinho, Acre (drawings by Joanna Troufflard); (**g**) – stone axe, site Ramal Batista, Acre; (**h**) – fragment of an anthropomorphic vessel, site Tumichucua, Bolivia (Photo: Sanna Saunaluoma); (**i**) – incised vessel, site Fazenda Atlantica, Acre (Photo: Sanna Saunaluoma)

speak of them as places where human beings would feel small and insignificant before a superior being. The fact that some enclosures display smaller enclosed areas might mean that special and secluded rituals were performed there (Saunaluoma and Kristiina Virtanen 2015). Some individuals must have enjoyed certain prerogatives, although there is no evidence for overt centralization.

Earthwork Sites in Rondônia

In Rondônia, earthwork sites occur in various parts of the state, but their location is biased by deforestation, since most of them have been identified by satellite imagery. Therefore, even if sites are likely to exist in the central and north of the state, the 120 recorded sites (with 136 enclosures) are mostly visible in the south, next to the Bolivian border. Thedata available for Rondônia sites comes from a study completed for the Institute of Patrimony in Brazil, which included remote sensing in deforested areas and limited ground survey in the west part of the state (Schaan 2014a).

Next to Acre and Amazonas, sites are mostly square, but as one moves toward south and east, for over 500 km, closest to Bolivia, sites began to look less geometric and are larger and mostly circular, similar to the ones found in Riberalta (Fig. 6). The most common shapes are squares and circles, but there are ditches shapes like U and D. More than 85% of the sites are comprised of a single enclosure, but there are sites with up to four ditched enclosures. All enclosures in the state are excavated ditches and adjacent embankments formed by the deposition of the excavated soil. There are no other earthwork features, such as lineal mounds, double ditches, moat enclosures, etc. Only seven enclosures, located next to the Acrean border, are connected to roads.

There is a lot of variability in terms of size: diameters range from 60 to 577 m, with a mean of 241 m. Here, the area of a single enclosure might

Geometric Earthworks of Western Amazonia, Fig. 7 Excavation profile of a ditch in the site Pastor Sapucaia, Acre. (**a**) – Site Pastor Sapucaia (Photo: Diego Gurgel); (**b**) – Perfil; (**c**) – excavation (Photo: Antonia Barbosa)

measure more than 20 football fields! The circular enclosures are the largest ones; their mean diameter is 100 m greater than the mean diameter for the square ones. There are other differences that definitely set apart the enclosures of the east from the west of Rondônia. For example, the ditch width, which is similar to Acre in the west (11,41 m), gets a lot smaller as one approaches the east, where it measures only 6,4 m in average.

The earthworks in Rondônia are more similar to the ones in Riberalta (below), because many of them are located very close to small streams, which suggest some form of water management or agricultural purposes. Unfortunately these sites in Rondônia have not been the focus of field studies and excavations, so there are no dates associated to their construction and use. There is no available ethnohistorical information about the people who build them.

Earthwork Sites in Bolivia

Different from Brazil, where earthwork sites have been constructed as primarily ceremonial, in Bolivia they are interpreted as permanent settlements (Saunaluoma 2013), although other functions have also been proposed. Indeed, since most of the sites have been used for long periods of time, most likely functions have changed through time (Erickson et al. 2008). Defensive purposes have been proposed by several researchers

(Arnold and Prettol 1988; Arellano 2002; Prümers 2014), a hypothesis that has been backed up by ethnohistorical sources that mentioned habitation sites with moats and palisades as defense against the expansionist and anthropophagous Guarani (Denevan 1963; Erickson et al. 2008).

More than a hundred earthwork sites are known in Bolivia, from the frontier with Acre to the northeastern part of the country (Fig. 7). Sites that have been the focus of studies are located in the seasonally flooded Baures region, where ditched enclosures and other earthworks cover an area of 12,000 km^2 (Erickson 2010) and in the Riberalta area at the confluence of the Madre de Dios River and the Beni River. In Baures, intensive surveys have identified 79 ditched earthworks (locally called "zanjas circundantes") including circular, oval, octagonal, hexagonal, quadrangular, or "D" and "U" forms (Erickson et al. 2008). In the Riberalta region of the Madre de Dios River, 26 earthwork sites are found inland or in the high river bluff. Five of them were studied and dated from 200 BCE and lasted until the European contact (Saunaluoma 2010). In the Llanos de Mojos, early indicators of earthmoving started by 900 BC, but the build environment related to agricultural activities and fish farming, indications of human settlements and the alteration of the savanna, and the active use of the massive earthworks related to agricultural activities took place between 400 BC and AD 1500 (Erickson 2010).

In the region of Riberalta, Saunaluoma studied 11 sites, of which 9 were the focus of systematic excavations. These sites have circular and linear ditches; one of them displays a circular embankment around an open area of 350 m of diameter. Sites are located next to the right bank of the Beni River, some of them near oxbow lakes, and others next to the Madre de Dios River. Some are located in the floodplain, others in high bluffs. In both cases, however, was clear the idea of locating next to a navigable river, different from Acrean sites, which were placed on the top of river valleys. Saunaluoma (2010) feels that the active movement of the Beni River might have played a role in the abandonment of some of the sites. This is because the region was occupied in two different periods: from 100 BC to 400 AD and, later, from AD 1200 to the conquest. Excavations yield mostly pottery sherds, which, according to Saunaluoma (2010), are part of the same cultural tradition. A human modeled head with coffee bean eyes recovered at the Tumichucua site is similar to the Barrancoid tradition (Fig. 6-H), which Lathrap (1970) equates with the Arawak expansion.

Erickson and colleagues have studied the ring ditches of the department of Beni, in the Baures region (Northeastern Bolivia). Some sites had up to four enclosures. Areas range from 1 to 5 hectares and ditch depth up to 4 m; ditch width measures in average 10 m (Erickson et al. 2008). There, ring ditches occupy areas of more than 1 km^2, sometimes with concentric multiple ditches. As in Acre, they were formed through the excavation of large, continuous ditches, up to 4.5 m deep and 10 m wide, "on forest islands or bluffs overlooking savannas, wetlands and rivers" (Erickson 2010). The function of such gigantic structures are multiple, such as "defense, settlements, elite residences, land and resource markers, animal traps, cemeteries, water management features, and/or pubic ceremonial spaces." Ethnohistorical accounts stated that many settlements in the Baures region were encircling by palisades, e.g., large trunks of trees aligned and placed closely to each other. This would require additional clearing; Erickson calls the region an engineering, cultural landscape, to stress the fact that not only humans build these large enclosures but also managed the space between them. This has caused an immense turnover of species which Balée (2013) calls secondary transformation of landscape.

The excavation of the site of Chipeno 1 ditch permitted to conclude that the north wall was more abrupt than the south wall and that the original depth was 2 m. The archaeologists believe that this ditch had a defensive function. The few potsherds found during the excavation included a fragment of an anthropomorphic figurine (Erickson et al. 2008). At the same time, they did not find evidence for domestic activities; thus both the figurine and the presence of fragments of large vessels, probably for the consumption of Chibcha, suggest a ceremonial usage for these sites.

Different from the Brazilian sites, here, in the Llanos de Mojos, the enclosures are associated with many other types of earthworks and some even with terra preta (Amazonian Dark Earths, ADE). The ditches in general enclose a so-called island of forest, a portion of elevated land that stands above the water level during the flood season. In the Baures complex, ditches are indirectly associated with walkways, canals, fish weirs, and fishponds, while in other places, they are associated with canals and raised fields and not with fish facilities (Erickson et al. 2008).

The only report on the use of an earthwork site as a cemetery comes from extensive excavations performed at the Bella Vista region (site BV-2) by Heiko Prumers. The archaeologist has recovered 16 funerary vessels containing poorly conserved human bones. It was possible to distinguish a funerary pattern: the individual was placed in a hole and covered with an upside-down globular vessel, which bottom was taking out. The was covered with the vessel bottom and other fragments. Funerary furniture is scarce and made of polished stone (in two cases) and vessel fragments. The burials were dated to AD 1300–1400 (Prümers 2014).

Paleoecological research in Northeastern Bolivia, as in Acre, has demonstrated that people did not have to clear large patches of forest in order to excavate the ditches, because they already lived in open savanna landscape. In fact, they were able to maintain the open savannas around their settlement even when rainforest began to expand some 2000 years ago (Carson et al. 2014). Erickson has suggested that the savannas were the result of centuries of manipulation of landscapes, with the use of fire. This has another important implication, since the fact that excavating ditches in the savannas implies less labor, than previously supposed, it would also imply lower population density (Carson et al. 2014).

Who Built the Geometric Earthworks?

In 1887, coming from Manaus, Coronel Labre ascended the Madeira River, hoping to find a land route between the rubber posts at the Madre de Dios River and a navigable point at the Acre River. They aim to build a railroad to connect Manaus and Bolivia through the Purus River. Departing from the Maravilha Port, at the Madre de Dios, Labre walked to the Acre River. In his way, he found many Araona villages (Tacana linguistic family). One of these, next to the border with Acre, had temples in the woods, where they reportedly kept effigies of their geometric gods. The father of all gods was shaped as an ellipse and called Epymará. This happened in a region full of geometric enclosures, but Labre does not describe them, probably because these were sacred places, kept away from intruders.

In Amazonian archaeology, it is difficult, if not impossible, to relate archaeological groups to present-day known ethnic or linguistic groups. The reasons are many, but all have to do with the history of migrations and alliances typical of Amazonian indigenous peoples after the conquest and maybe even before. As natives retreated away from the contact zones, escaping from the enslavement expeditions and running away from diseases and war, they would regroup with peoples with different ethnic backgrounds forming new supra-ethnic organizations. In the new land, centuries of cultural change later, they have lost the memories of the earthworks, and most of them do not fabricate ceramics. There has been a long tradition in Amazonian archaeology, beginning with Lathrap, to relate pottery traditions to particular ethnic groups, but, with the probable exception of the ethnohistorical Tupi-Guarani, whose pottery have been used as a cultural marker, such attempts have no sound evidence to support it.

Michael Heckenberger associates earthworks with Arawak speakers, explaining that the Arawak diaspora over a huge area of the Amazon periphery coincides with earthmoving activities. However, in the upper Xingu case were the Kuikuru (Carib language family) who is responsible for both building moat-fortified villages and carrying along the Arawak sense of regionality (Heckenberger et al. 2008).

It would, however, be impossible to think that only one ethnic group would be responsible for all the earthwork sites in Western Amazonia. Not only because of the huge area that they would

have dominated for centuries but also because the sites speak about variability of purposes and layouts. Ethnohistory places the Arawak, the Panoan, and the Tacana in the border between Bolivia and Brazil and the Baure in the Itenez Province, in Northeastern Bolivia. These were most likely the groups who built the multipurpose, gigantic enclosures over more than a millennium.

In Bolivia, the ring ditches are part of a vast complex of earthworks that include roads, raised agricultural fields, fish weirs, mounds, causeways, and canals, which impressed the first Spaniards who got there in the beginning of the eighteenth century (Denevan 1966; Erickson 2010). These people were described as highly civilized, with government, clothing, religion, etc., but they rapidly vanished though, with the spread of diseases, enslavement, and war. This situation stopped the maintenance of earthworks, and most knowledge pertained to that was lost before a good ethnography could register it.

Virtanen, a finish anthropologist, has worked with the Apuriña and Manchineri (Arawak speakers) in Acre, among other things, investigating their relation to the geometric enclosures. These two groups dominated the Upper Purus River Basin at the time of the first effective contacts, in the nineteenth century. Although they have no recollection of the earthworks, she argues that in their cosmology and mythology, they convey concepts closely related to the earthworks shapes, location, and landscape features (Figs. 8 and 9).

Future Research

After some 15 years of intensive studies of Western Amazonian earthworks, many questions are still waiting for answers. Although it has become clear that the rind ditches were a cultural phenomenon, a building technique used by many peoples to organize spaces of living, leisure, work, and

pray, the specificities of activities taken place in a given enclosure are not totally clear. Questions on demography, also extremely important, have not been adequately addressed. These questions are tied to the low densities of cultural debris found in the sites and fail to find other non-earthwork sites which might have housed the earthmovers elsewhere. Recent research on multiple-mound sites in Acre have showed that such occupations, although somehow related to geometric enclosures, are later than most of earthworks, thus not solving the problem.

In the next years, ceramic studies, focusing on loci of production, might help to verify or falsify the hypothesis that states that many people from different places gather in the enclosures for some time during the year, bringing their vessels with them. This would proof the use of the earthworks as meeting places for peoples who lived elsewhere.

A hot topic in Amazonian archaeology, in close relation to the geometric earthworks, is the extent to which humans have modified the landscapes. This question is not a simple one and must be addressed taking in consideration, of course, archaeological data. This is because it has become clear that the Amazon basin hosted different cultures and peoples over time and that the impact they caused on the landscapes was highly variable (Schaan 2014b). It is why research focus only on paleoecological data, detached to archaeological data, tends to be misleading. We know through archaeology, ethnography, ethnobiology, and ethnohistory that humans have greatly modified the Amazon forest and that much of its biodiversity is consequence of human management (Balée 2013; Levis et al. 2017).

A new technology in Amazonian archaeology is supposed to make a revolution in earthwork research in the next few years. It is the Lidar, a laser sensor capable of making a topographic map of the earth's surface in forested areas. Since most of the sites have been found using satellite imagery, which depends on areas free of vegetation, the

Lidar will solve the problem of survey bias, and we finally will be able to have an accurate account of the number and of the variability of geometric earthworks in Amazonia.

Geometric Morphometrics and Environmental Archaeology

T. Krish Seetah
Department of Anthropology, Stanford University, Stanford, CA, USA

Introduction

History and Development of Geometric Morphometrics

The study of biological shape (morphometrics) involves the analysis of anatomical variation of an organism or its constituent parts. Geometric morphometrics (GMM) has taken advantage of contemporary developments in computing technology and statistical objectivity to establish a means of shape analysis that is mathematically derived, allowing comparisons of shape to be performed quantitatively. The main advantage that GMM has over traditional morphometrics (TMM) is that the latter inherently deals with size, not shape. While descriptions of size variation are useful, shape can inform on a greater range of biological processes, such as ontogeny, and adaptation to specific ecological niches (Zelditch et al. 2004).

Morphometric analysis is rooted in biological research with key advances made during the last decade. However, if one considers that both taxonomic classification and our understanding of biological diversity are based on morphological variation, it is evident that the analysis of *shape* has been an underlying tenet of biological research for centuries (Adams et al. 2004). D'Arcy Thompson is credited for his pioneering work on geometry and biology, which paved the way to modern morphometrics, demonstrating how simple changes in the body part proportions of an organism could "transform" it into another (Fig. 1, adapted from Thompson 1917). With the advent of computers, the early theory of shape analysis found practical applications that had previously been impossible to perform. The field effectively underwent a revolution in the early 1990s (Rohlf and Marcus 1993) with the development of robust statistical models for testing variations in shape and size between organisms, and of sophisticated computerized tools for the visualization of these differences.

Performing GMM Analysis: Landmark Configuration, Digitization, Superimposition, and Visualization

As a broad simplification, morphometric techniques can be two- or three-dimensional and use either landmarks on, or the outline/surface of, the organism (or its morphological part/s) being studied.

The landmark technique relies on the anatomy of the organism to provide distinct, nameable, loci that have clear one-to-one correspondence from one specimen to the next (e.g., the apex of a leaf, the meeting point of frontal and parietal bones in the skull, the intersections of homologous veins in a fly wing). The type of correspondence of landmarks, or "homology," varies depending on the specific context within a morphometric analysis. Biological homology can be loosely derived: for example, the hind limb of a lion can correspond to the hind limb of a gazelle in terms of its development and evolutionary origin. The wing of a bat and that of a bird, in contrast, originated independently and differ in development but could still be analyzed in terms of correspondence in a study on flight biomechanics. The choice of the landmarks and the type of correspondence are, therefore, functional to the specific hypothesis being tested. Numerically, Cartesian coordinates along two or three axes univocally define each landmark.

Although morphometric techniques have tended to favor the landmark approach with the majority of applications in 2D, this is not always applicable, as on occasion, landmarks are not available, practical, or replicable. The outline method was the first attempt to address this issue by using the delineation around the curvature of an organism or its parts (Bookstein 1997: 44–45) discretized by a series of ordered points along its contour. Recent advances in morphometric research have led to the development of 3D quantitative imaging techniques that extend the outline approach to surfaces. In general, 3D methods tend

Geometric Morphometrics and Environmental Archaeology, Fig. 1 Adapted from D'arcy Thompson's (1917) original depiction, illustrating the transformation of *Argyropelecus olfersi* into *Sternoptyx diaphana* through a 20° shear

to be more accurate as most biological structures are not flat objects, i.e., a fly wing, but are highly complex organs, i.e., the skull.

Once landmark coordinates have been captured, termed digitization and employing data from a basic digital camera to sophisticated MicroScribe digitizers or CT scans, the first step in the process of analysis is to remove the information that does not alter shape, that is, translation, rotation, and scale (Fig. 2).

One method that has been particularly favored for this function is the Procrustes superimposition. This method scales the centroid (a mathematically derived midpoint, hence centroid, between all landmarks, Fig. 3) size of each specimen, makes the centroid the new common origin of the Cartesian space, and minimizes differences in rotation to produce shape data that can then be statistically analyzed (Fig. 4). Importantly, while the size data are removed, they are not lost and can be used for comparisons between groups.

Visualization follows and, in one of its most common forms, reverts to the basic tenet described by Thompson (1917), albeit with a greater degree of sophistication. Visualization of shape changes relies on a principle derived from engineering whereby a thin sheet of metal, on which a grid may be superimposed, is deformed in order to illustrate the variations that occur *between* the landmarks, when one shape is warped until it overlaps with the points of a different shape. This method of visualization, termed the thin plate spline (TPS), has been adopted by James Rohlf for his widely used and arguably one of the most important software packages for GMM, the TPS Suite (http://life.bio.sunysb.edu/morph/). Whether using the TPS software or other programs, the principle remains the same: to intuitively illustrate shape variation between specimens using a deformation grid (Fig. 5). Other more sophisticated diagrams and techniques include contour, surface, and volume rendering. In tandem with visualization methods is the obvious need to interpret and understand "shape space," distances, and directions of any observed variation (Klingenberg and Monteiro 2005). Principal components analysis (PCA) has proved to be a highly popular exploratory technique for this (Zelditch et al. 2004: 156), and more recently, the "R" language has increasingly been employed for the statistical analysis of GMM datasets (Claude 2008).

Applications of GMM

In terms of relevant applications, GMM has been widely employed within comparative zoology and biological/physical anthropology. Furthermore, it is by no means restricted to studies of vertebrate fauna and has been applied to arachnids (Crews and Hedin 2006), echinoderms (David and Laurin 1996), crustaceans (Aguirre et al. 2006), and hemiptera (Dujardin et al. 2007). Indeed, application of the technique is not limited to fauna and has been applied to plants (Viscosi and Cardini 2011). Given the ubiquity of plant, pollen, and insect remains on archaeological sites and their

significance for studying paleoenvironments, for the paleobotanists, palynologists, and palaeoentomologists, these latter examples will no doubt serve as increasingly important for future research.

While the above exemplifies the diversity of application of GMM, and despite the variety of species and range of research themes that this method has been employed to study, to date, it has not been as widely applied in archaeology as

one might expect. This is especially surprising where zooarchaeology is concerned, particularly when one takes into account the long history of use in zoology. This should not be taken to suggest that GMM has not been employed to study the archaeological or fossil record. In the same way that the technique itself underwent dramatic developments over the last two decades, it is now undergoing a revolution with regard to application, which will ultimately have implications for its use in archaeology.

When the technique has been employed, it has proved to be highly effective. Cucchi et al. (2011) showed how trends in pig domestication could be interpreted using morphological variation and phenotypic divergence; research has also shown the potential of this method for identifying discrete populations of a species within a spatial-temporal framework (Seetah et al. 2012). Questions of wider significance have also been investigated: Larson et al. (2007) addressed issues of human dispersal in Island SouthEast Asia, using domestic animals as a proxy and employing GMM in combination with molecular techniques. The large-scale migration, and ultimately the importance of horse as a source of subsistence for humans in Western Europe, was studied from Magdalenian sites within the Paris Basin (Bignon et al. 2005) using GMM.

Definition

Geometric morphometrics is, in its most common implementation in evolutionary biology and related disciplines, the analysis of size and shape derived numerically from landmarks (topographically corresponding points) on biological/nonbiological organisms.

Key Issues/Future Directions/Examples

Arguably one of the main issues with regard to using GMM is that, despite the considerable potential for application to a variety of fields including archaeological research, developments made in the mathematical theory of shape were slow to be adopted into mainstream research due to jargon and statistical complexity. These issues have now been addressed with notable developments in both textbooks (Zelditch et al. 2004; Claude 2008) and software to facilitate statistical analysis (MorphoJ/Morphologika/Morpheus, IMP series, PAST, etc. – refer to http://life.bio.sunysb.edu/morph/soft-comprehensive.html).

Despite improvements, statistically analyzing the complex datasets that GMM produces requires some caution and may not be without pitfalls. The advent of advanced software with easy-to-use interfaces, while circumventing much of the complexity, has the negative outcome of detaching the analyst from a clearer understanding of the mechanics behind the analysis, an issue most detrimental for the novice. Additionally, the more complex statistical aspects of GMM data analysis and interpretation can occasionally lead to a misrepresentation of what is possible (at present) with the outcomes of GMM analysis (see Adams et al. 2011 for a discussion of the limitations of principle components (PC) for cladistics analysis).

Once these, often subtle, potential issues are clarified, and with step-by-step analytical examples available in the literature (Viscosi and Cardini 2011), there should be few barriers to the widespread application of GMM in environmental archaeology. Although there is little doubt that GMM can be applied to a very wide range of biological systems, in archaeology it is the study of bone, and in particular animal bone, that will invariably benefit the most from this method. GMM has two main applications in this regard: investigating phenotypic changes in populations and understanding ecomorphology (divergence in form as an adaptation to the environment). In the former case, as a first step, the landmark data may simply be compared between groups in order to identify significant morphological variation. This can then be used as a means of classifying unknown individuals using cross-validated models derived from well-known samples. In the latter, a more complex understanding of the animal's anatomy is achieved through cross-group comparisons (i.e., different species of bear) in relation to their ecology, often using modern populations to model variation in the past.

Ancient specimens are then projected into the shape space and similarities with modern counterparts used to infer past behavior (see Figueirido et al. 2009, using extant and extinct bears).

One of the main strengths of GMM is its inherent compatibility with complementary techniques to explore a greater range of questions that are pertinent to archaeological research. Though this is very much underexploited, there is much potential in combining GMM with both molecular methods, such as DNA, and morphological techniques, such as finite element modeling (FEM). DNA can provide evidence detailing evolutionary history, the role of drift and selective pressures, as well as other processes that may leave a genetic signature. FEM uses stress modeling to interpret load bearing and force capabilities of different parts of an organism's body, which can be used, for example to infer bite force and thus indirectly inform on diet, ecology, and behavior. GMM data not only provide quantitative phenotypic information that can be mapped onto the genetic landscape obtained from molecular analyses to explore the tempo and mode of evolutionary change but also allow the multivariate comparison of deformations from FEM-computerized experiments and the analysis of their covariation with predictors (environment, genetics, etc.) in an accurate statistical biomechanical framework. Taking this approach a step further, by combining the evidence from phenotypic and genetic studies with those that detail environmental conditions in deep time, it should be possible to position fauna into a more appropriate "archaic ecological niche."

Ultimately, GMM allows archaeologists to use modern biological approaches to investigate deep-time phenomena. The consensus remains that environmental samples from archaeological contexts, and bone in particular, are often too fragmented or scarce to carry out the type of rigorous experimentation that details past ecological systems. However, while the physical numbers may not compare with those available to contemporary biologists, for the environmental (and indeed "biological") archaeologist, by using species that occur in considerable abundance, such as the cave bear (Europe) or dire wolf (North America), it is possible to carry out the type of studies that are being performed on modern faunal populations (Cardini et al. 2007). Fragmentary material could still be fruitfully analyzed (Hublin et al. 2009) and incomplete fossils reconstructed (Gunz et al. 2009). The method could be instrumental in understanding the process of domestication and its outcomes (such as paedomorphism), as well as the mechanism promoting island dwarfism/gigantism and the role of allometry (the covariation of shape and size) in creating phenotypic variation, and other recurrent phenomena observed in species that underwent domestication.

GMM may well underpin a trend toward the type of interpretive studies that bridge a gap between contemporary biological and ecological studies and those concerned with adaptive changes through time as a consequence of environmental fluctuations and agency. Given its scientific rigor, the fact that it can be relatively inexpensive to perform and the range of questions it can potentially provide evidence to address, it would be a great surprise if this method does not enjoy the type of widespread application currently witnessed for DNA and isotope analysis.

Gero, Joan

Pamela Geller
Department of Anthropology, University of Miami, Coral Gables, FL, USA

Basic Biographical Information

Joan Margaret Gero was one of the leaders in the sociopolitics of archaeology, feminist archaeology, and Andean archaeology. She was born on 26 May 1944 in New York City and grew up in the city's suburbs. The countercultural movement served as historic backdrop for her undergraduate

years at the University of Pennsylvania. Social activism and the seeds of feminist thinking were planted at this time. Gero graduated in 1968 with a B.A. in English Literature. In 1970, she received a M.Ed. from Boston College and then worked for Teacher Corps, a domestic program that educated the socioeconomically disadvantaged. Enamored with the Corps's commitment to equality, the experience offered an important anthropological lesson about cultural differences in the classroom and community. After 2 years of teaching, Gero revisited the role of a student. During a summer exchange program at Oxford, she enrolled in an archaeology course that involved excavation of an Iron Age site in Wiltshire.

Gero returned to the USA in 1973. She attended classes in archaeology at Harvard and excavated at Chan Chan, Perú, under Michael Moseley's aegis. This fieldwork served as a springboard for her ongoing investigations of Andean prehistory. In 1974, Gero commenced graduate studies at the University of Massachusetts, Amherst. Several personal experiences during this time shaped her theoretical approach to archaeology. Sexism, as Gero soon discovered, was the status quo. Doctoral research in 1977 was initially hindered by a supervisor who questioned the appropriateness of a woman living in the project house, and many colleagues found research about ancient women implausible. Despite these obstacles, Gero completed her dissertation, which examined material culture's active social roles. In 1983, she was granted a Ph.D. in Anthropology.

Gero accepted a position in the University of South Carolina's Department of Anthropology where she taught from 1983 to 1997. She was hired as Assistant Professor at American University in 1998 and retired as Professor Emerita in December 2007. She held several visiting appointments – at England's University of Cambridge, Sweden's University of Umeå and Uppsala, and Argentina's Universidad Nacional de Catamarca and Universidad Nacional del Centro de la Provincia de Buenos Aires. From 1996 to 2016, Gero was a Research Associate at the Smithsonian Institution's Department of Anthropology. Throughout her career, she received grants from the National Endowment for the Humanities, National Science Foundation, Fulbright, Wenner-Gren Foundation, and Heinz Foundation. In 2007, Gero was awarded the Squeaky Wheel by the American Anthropological Association's Committee on the Status of Women in Anthropology.

Major Accomplishments

Gero was long committed to the radical transformation of archaeology. To this end, her investigations of the past incorporated feminist perspectives and addressed contemporary politics at global and local scales. Her earliest writings reveal the crystallization of perduring research interests. Notably, the publication of *The Socio-Politics of Archaeology* (Gero et al. 1983) called for sociological analysis of the field and its epistemological production. For her, critical consideration of North American archaeology ran parallel to, not in the wake of, paradigmatic shifts in British postprocessual archaeology. Gero's (1983) own chapter identified the gendered segregated nature of research; men predominated in the field, while women labored largely at museum studies and lab analysis. She continued to hone these arguments about inequities and expectations in the influential article "Socio-Politics and the Woman-at-Home Ideology" (1985). These writings were inspired by Gero's early experiences conducting fieldwork in Perú. In making the personal (and political) the professional, her feminist approach exposed and challenged the discipline's pervasive androcentrism, as well as questioned normative ways of thinking about the past.

One of Gero's major contributions was the fomentation of feminist archaeology. She is best known for *Engendering Archaeology* (1991), the volume she co-edited with Margaret Conkey. The now-canonical volume, which began as a 1988 conference titled "Women and Production in Prehistory," destabilized assumptions about men's societal contributions, legitimated gender as an issue for investigation, and effected more holistic understanding of ancient societies. In her chapter, Gero (1991) identified the implicit sexism in

Paleoindian archaeologists' studies of tool production. Building on her knowledge of lithics, she deconstructed "Man the Toolmaker" and the undue emphasis this notion places on supposedly "male-only" activities (i.e., hunting, butchering). She then argued for women as manufacturers of stone tools. Affirmation of women's roles and abilities, Gero concluded, laid important groundwork for more nuanced reconstructions of gender systems and social transformations. With gender's analytical validation, Gero's feminist concerns expanded. She examined the complex gendered arrangements of ancient households in Argentina, arguing that social relations often defy easy dichotomization as hierarchical or complementary (Gero and Scattolin 2002). Engagement with feminist perspectives also provided a basis for the querying of taken-for-granted evidence. In her study of Recuay pots from Perú, for instance, Gero (2004) deliberated about the sociopolitical significance of their graphic sexual couplings. Her final contribution to archaeological theory and Andean archaeology was *Yutopian: Archaeology, Ambiguity and the Production of Knowledge in Northwest Argentina*. In this 2015 book, Gero provided an account of excavations at an Early Formative village in the southern Andes (Gero 2015). Offering a new model for the site report, she explored the interplay between archaeologists' fieldwork experiences and their production of knowledge.

Gero's engendering of and subsequent contributions to feminist archaeology emphasized her concern not just for the theoretical and topical but also for disciplinary politics and remediation of asymmetrical power relations. Her archaeological praxis promoted social justice. Dedicated involvement in the World Archaeological Congress (WAC) signaled one means to an equitable end. The organization subverts traditional archaeology born of colonialism, and it gives practitioners who have been historically marginalized – due to nationality, ethnicity, and economic disadvantage – an opportunity to shape practice and theory. Gero wore many hats in WAC. She was elected the North American representative from 1999 to 2008 and served on the Standing Committee on Ethics from 2007 onward. In June 2003, Gero acted as Academic Secretary for WAC-5 in Washington, DC, a congress of particular importance given its attendance and international visibility. From 2003 to 2010, Gero was Head Series Editor for the *One World Archaeology* book series. Gero's own contribution to the series, coauthored with Dolores Root, argued that *National Geographic*'s portrayal of archaeology endorsed a nationalist ideology of American expansionism and capitalism (1990). In 2012, she and husband Stephen Loring received the Lifetime Achievement Award from the World Archaeological Congress.

In sum, Gero worked throughout the duration of her career to realize an archaeology that is fully self-aware, less exploitative, and more collaborative. She died on 14 July 2016, a beloved and inspirational figure in the field.

Gerstenblith, Patty

Patty Gerstenblith
DePaul University College of Law, Chicago, IL, USA

Basic Biographical Information

Dr. Gerstenblith earned her A.B. from Bryn Mawr College in Classical and Near Eastern Archaeology, Ph.D. from Harvard University in Art History and Anthropology, and J.D. from Northwestern University School of Law. Upon graduation from law school, she clerked for the Honorable Richard D. Cudahy of the US Court of Appeals for the Seventh Circuit. She is a Distinguished Research Professor at DePaul University College of Law, where she also acts as Director of the Center for Art, Museum and Cultural Heritage Law. She is a co-director of the Tulane-Siena Institute for International Law, Cultural Heritage and the Arts.

Major Accomplishments

Dr. Gerstenblith served as the Chair of the President's Cultural Property Advisory Committee, a federal advisory committee in the US Department of State, in the Obama administration from 2011 to 2017, and had served previously as a Public Representative in the Clinton administration from 2000 to 2003. She serves as the Secretary of the Board of Directors of the US Committee of the Blue Shield, is a Consulting Scholar at the University of Pennsylvania's Museum of Archaeology and Anthropology, is a member of the Editorial Board of the UK journal *Art Antiquity and Law*, and is a member of the Steering Committee of the American Bar Association's International Art and Cultural Heritage Law Committee. Prior to these appointments, she was Editor-in-Chief of the *International Journal of Cultural Property* (1995–2000) and the founding President of the Lawyers' Committee for Cultural Heritage Preservation (2006–2011). She has held several offices on the International Art and Cultural Heritage Law Committee of the American Bar Association's Section on International Law. She has served as a trustee of the Archaeological Institute of America, the American Schools of Oriental Research, and the Albright Institute of Archaeological Research and was a member of the American Alliance of Museums Task Force on Direct Care of Collections. She was an advisor to the Past for Sale project of the Neubauer Collegium for Culture and Society at the University of Chicago and an advisor to the Countering Looting of Antiquities from Syria and Iraq Project at George Mason University.

Her main areas of research and publication are the international trade in archaeological and cultural artifacts, museum acquisitions policies, and the protection of cultural heritage during armed

conflict. Among her publications is the casebook, *Art, Cultural Heritage and the Law* 4th ed. (Gerstenblith 2019). She is the author of more than 80 articles and has contributed to several amicus curiae briefs in cases involving cultural heritage issues. She has spoken at conferences, universities, and museums throughout the world and is interviewed in the 2016 documentary, *The Destruction of Memory*, produced by Tim Slade. In 2018, she received the Championing Cultural Heritage Award from the Archaeological Institute of America and the Antiquities Coalition.

Getty Foundation

Andrew Thomas Wilkinson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

G

Basic Information

The Getty Foundation (http://www.getty.edu/foundation/index.html) functions as a philanthropic arm of the J. Paul Getty Trust. Originally based in Santa Monica, the foundation is now administered from the Getty Center in Los Angeles, USA. The Getty Grant Program was announced on the 11th of October 1984 and assumed its current title in 2005 reflecting the changing needs for funding support (About the J. Paul Getty Trust n.d.). The initial motivation was to provide a source of funding for the visual arts and in particular "...works of exceptional merit" (Administrative History n.d.). From 1985 the early grant categories comprised library and archival projects at independent centers for advanced research in the history of art, scholarly cataloging of art museum collections, publications, conservation, museum programs to interpret permanent collections, education in the arts, and national and international service organizations (Administrative History n.d.). The postdoctoral fellowship program which was previously administered externally commenced at the Getty Museum in 1986.

From 2005, key priorities were established to assist "...individuals and institutions committed to advancing the greater understanding and preservation of the visual arts in Los Angeles and throughout the world" (About the Getty

Foundation n.d.). These areas are supported by the Getty Foundation in conjunction with collaborative programs offered by the Getty Research Institute, the Getty Conservation Institute, and the J. Paul Getty Museum. The foundation currently focusses on four strategic areas based upon:

- Access to museums and archival collections
- Art history as a global discipline
- Advancing conservation practice
- Leadership and professional development

By the year 1990, 530 grants had been distributed to 18 countries, amounting to funding of US$20 million (Muchnic 1990). Between 2002 and 2011, nearly 100 grants, totaling US$11 million, were awarded to the *Pacific Standard Time* project alone, which began as an archiving project for postwar art in Los Angeles. In August 2012 US$1.95 million was granted to the Getty Leadership Institute, which relocated to Claremont Graduate University in 2010, as a 3-year commitment to ensuring the leading-edge development of museum professionals. The Getty Trust produces numerous publications with many works resulting from research funded through the Getty Foundation.

Applications for funding are competitive and must meet stringent selection criteria. Residential Grants and Fellowships for the Getty Research Institute and the Getty Conservation Institute, as well as Graduate and Undergraduate Internships are accepted online.

Major Impact

Since inception, the Getty Foundation has awarded significant grants to projects around the world. In 2012, 28 grants totaling more than US$1.3 million were given in the Access to Collections category. For the 2011–2012 period, seven grants ranging between US$48,000 and US$310,000 were allocated to five countries to enable international exchange among scholars in art history. A further seven grants, totaling approximately US$1.9 million, were also awarded in Conservation for the same period. To encourage professional development, undergraduates were included among 115 internships awarded in 2012. In the same year the foundation administered 83 residential grants (J. Paul Getty Trust 2012).

Examples of the range of projects the Getty Foundation has supported include:

- 2005 National Trust for Historic Preservation, Washington, DC. For an assessment of damage to historic structures in the Gulf Coast region affected by Hurricane Katrina. US$100,000
- 2008 New Orleans Jazz and Heritage Foundation, Inc., Louisiana. For a conservation survey of the foundation's archives. US$25,000
- 2008 West African Museums Program, Senegal. For training in the preservation of historical photographs. US$200,000
- 2008 International Council of African Museums, Kenya. Assist in the organization restructure to better serve the African museum community. US$175,000
- 2010 Conservation of the *Ghent Altarpiece* and Vasari's *The Last Supper*. €630,000
- 2011–2012 University of Sydney, Australia. For a series of planning meetings to assess the status of the history of modern and contemporary art in Southeast Asia. AU$94,000
- 2011–2012 The British School at Rome, Italy. For a workshop on protective shelters for archaeological sites. €78,000
- 2011–2012 Association Internationale des Critiques d'Art, Paris, France. For participants from developing countries to attend the 2012 Congress in Zurich, Switzerland. US$43,600

Glacial Advances in Asia, Europe, and North America

Sureyya H. Kose
Department of Chemistry, Curtin University, Perth, WA, Australia
Department of Earth and Planetary Sciences, Macquarie University, North Ryde, NSW, Australia

Introduction

Glacial-interglacial cycles (when glaciations advance to their maximum and retreat to their minimum) have occurred throughout much of the Earth's climatic history (EPICA 2004). Presently, in the Holocene epoch, the Earth is experiencing an interglacial period of a glacial-interglacial cycle that began approximately 100,000–124,000 years ago within the Pleistocene epoch (Berger 2002). Glacial advances have not only covered vast expanses of Asia, Europe, and North America but the globe as early as 2.4–2.0 billion years ago within the Proterozoic eon, when the first global glaciation is said to have occurred (Strand 2012: 70). The most extensive glacial advance to have dominated the global landscape occurred between 800,000 and 600,000 years ago, with glaciers advancing to mid-latitudes (Strand 2012: 70). Giving this period the term "snowball earth," researchers, through studies of oxygen isotopes gathered from deep-sea ocean sediments and ice cores, have determined further glaciations at roughly 100,000-, 41,000-, 23,000-, and 19,000-year intervals (Berger 1992: 572; Berger 2002; Strand 2012: 70). The most recent glacial advance occurred approximately 18,000–24,000 years ago and reached its peak 21,000 years ago (Mix et al. 2001). Termed the "Last Glacial Maximum" (LGM), this event saw, once again, the advent of large expanses of Asia, Europe, and North America covered in a number of ice sheets (Mix et al. 2001).

Definition

Glacial advances or glaciations occur when layers of snow accumulate in an area where the local climate is cold enough to sustain the newly deposited snow during the summer. Each winter, as younger snow is deposited, the layers of older snow compact further. The pressure of overlying layers eventually increases, and the hexagonal points of snowflakes partially melt and bond together. After some time, the layers of snow turn into an increasingly solid material (approximately 25% air) called firn (Marshak 2009: 472–3). With additional layers of snow causing more pressure, melting, and recrystallizing, the firn becomes a solid of interlocking ice crystals containing less than 20% air trapped in bubbles (Marshak 2009: 472–3). These solid masses of ice are called ice sheets on sea or glaciers on land, can last year round, and can take from 10 to 100 years to many thousands of years to develop (Marshak 2009: 473). The two main types of glaciers are mountain glaciers and continental glaciers.

Continental glaciers accumulate much the same way as mountainous glaciers, but rather than flow from higher latitudes to lower latitudes with the force of gravity, continental glaciers flow outward as the precipitation of snow increases. Glacial thickness can be several kilometers to a few hundred meters in depth and can span continents.

During the Last Glacial Maximum, a number of continental ice sheets (Fig. 1) covered large areas of the northern hemisphere (Clark and Mix 2002: 2). The Laurentide and Innuitian ice sheets accumulated in and covered all of Canada east of

G

Glacial Advances in Asia, Europe, and North America, Fig. 1 The CLIMAP maximum model. Ice sheets are identified by letters: (*C*) Cordilleran, *L* Laurentide, *I* Innuitian, *G* Greenland, *B* British, *S* Scandinavian, *Ba* Barents Sea, and *K* Kara Sea (Clark and Mix 2002: 2)

the Rocky Mountains. These ice sheets advanced into North America with the greatest extent reaching southern Illinois (Marshak 2009: 491). The Cordilleran ice sheet covered the southern third of Alaska, including the Alaskan peninsula. In North America, mountain glaciers developed in the Rocky Mountains, Sierra Nevada, and the Cascade mountains (Marshak 2009: 491). The British ice sheet covered the majority of Ireland, Great Britain, and what is now the North Sea (CLIMAP 1981; Marshak 2009: 491). The Scandinavian ice sheet covered all of Scandinavia and northern Russia and reached the Swiss Alps. Northern Asia from northeastern Russia and Siberia to the higher latitudes of Tibet was covered by the Kara Sea and Barents Sea ice sheets (CLIMAP 1981; Clark and Mix 2002).

For the phenomenon of a global glaciation to occur, such as with the LGM, a drop in global climate had to occur. Factors that enable global cooling and glaciations have been attributed to the astronomical or Milankovitch theory (CLIMAP; EPILOG; Berger 1992). As the Earth travels on its elliptical orbit around the sun, it experiences certain variations in its eccentricity, axial tilt (also known as obliquity), and precession thought to arise by the orbital forcing of planetary bodies within the solar system. These in turn alter the amount of solar radiation that reaches the planet's surface thereby affecting seasonal and glacial-interglacial pacing (Rial 2004: 1, Schieber 2007). Although challenged in recent debates, the Milankovitch theory has maintained its validity through modern research techniques and a rigorous assessment of previous findings (Rial 2004; Huybers 2011; Strand 2012).

Key Issues/Current Debates/Future Directions/Examples

In the 1970s, the CLIMAP (Climate: Long range Investigation, Mapping, and Prediction) research project began a global collaboration to map the global extent of ice sheets and ascertain a definitive chronology for the LGM (CLIMAP 1981). In recent debates, their initial finding for the peak of the LGM at 18,000 BP has been in dispute. In 2001, the EPILOG (Environmental Processes of the ice age: Lands, Oceans, Glaciers) research project undertook a similar study and, with the aid of modern modeling techniques, found the peak of the LGM closer to 21,000 BP (Mix et al. 2001). A further debate involves the extent of the Kara Sea ice sheet in northwestern Russia (Clark and Mix 2002). The CLIMAP (1981) findings and geomorphic evidence indicate that a large ice sheet did cover this area (Grosswald and Hughes 2002). Clark and Mix (2002) and Mangerud et al. (2002), however, argue that a detailed look at the

chronological evidence suggests that the Kara ice sheet existed before the LGM at its onset and that the Kara ice sheets' extent was limited to the western region of the Novaya Zemlya.

Glacial Landscapes: Environmental Archaeology

Luis Alberto Borrero
CONICET-IMHICIHU, Buenos Aires, Argentina

G

Introduction

Glacial landscapes are distributed all over the planet, and they are present even in tropical regions. Hominins were necessarily involved with these landscapes, sometimes avoiding them, but many times developing means to adapt to them. The history of the advances and retreats of the ice during the Pleistocene shows that many of the areas where hominins lived after their initial radiation from Africa were characterized by glacial and periglacial conditions. Indeed, most of the process of hominin dispersal took place under very cold conditions. In most mountain areas, valley or cirque glaciers covered parts of regions that were eventually colonized by hominins. In many places, especially in the high latitudes of the northern hemisphere, periglacial environments were present even at sea level inhibiting or at least affecting the feasibility or continuity of human occupation in many places (Hoomard 2011).

Historical Background

The very first systematic accounts of the prehistory of humankind in Europe were organized by using a scheme of four Alpine glaciations, which now is known to be much more complicated, with a variable number of ice advances punctuating the

Pleistocene in different parts of the world (Bradley 1999). These ice advances affected the distribution of hominin populations mainly in Europe and Asia, restricting their distribution to the southern portions of those continental masses during millenia. By the end of the Pleistocene, *Homo sapiens* were present at most of the continents but were rare or absent in the extreme north (Straus 1996). During the Last Glacial Maximum (LGM) around 24–20 ka BP, many portions of the Northern Hemisphere were glaciated, a time during which many European human populations contracted to environmental refugia like the Iberian and Italian peninsulas. However, at a global scale the human response to cold glacial conditions was varied, ranging from dispersal to concentration (Gamble and Soffer 1988). The last significant ice advance of the Pleistocene was the Younger Dryas, a cold period characterized by its very fast inception that occurred in a matter of a few decades. It is dated around 11–10 ka BP – 12,900–11,600 cal BP – and it is known that it produced no important effects on populations living in central Europe (Jochim 2012) or North America (Meltzer 2009). However, this is a time during which the northern Netherlands, Scandinavia, and most of North America were not inhabited. In North America, human occupations were practically restricted to Alaska, Yukon, or the Southern Plains. On the other hand, it is not clear what was the importance of the Younger Dryas in southern South America or in Australia and New Zealand. However, late Pleistocene cold spells in synch with the Antarctic Cold Reversal were identified in the region of the Strait of Magellan, Southern Patagonia (McCulloch et al. 2005). As a result it must be inferred that the process of human colonization of southern South America took place under very cold conditions (Borrero 2012).

The colonization of Northern Europe or Northern Siberia required the availability of shelter, insulating clothing, and relatively sophisticated stone tool and bone technologies. It took hominins millions of years to be able to colonize these north cold periglacial habitats, and it was only with the advent of *Homo sapiens* that those regions were effectively reachable. In spite of claims for Neandertal's occupations at Byzovaya, near the Ural Mountains at 65 °N (Slimak et al. 2011), it must be kept in mind that this attribution was solely based on characteristics of the stone tools. This evidence is not strong enough to move 1000 km north the known limit in the distribution of Neandertals.

Specifically in Northeast Siberia, the hominin range apparently never reached above 55 °N during the early Upper Paleolithic, "and it was not until c. 25,000–20,000 BP that they inhabited the extreme continental north" (Goebel 2004: 195). This panorama, of course, implicates that the human entry to America took place under very cold conditions and relatively late in the Pleistocene. Even when most of the Beringian habitats were not glaciated, the conditions were difficult for humans. Palynological evaluations suggested that at that time Beringia was a barren landscape (Colinvaux 1986). However, the faunal vertebrate richness of Beringia – that characterizes the so-called Mammoth Steppe – surely facilitated the peopling process by providing an adequate subsistence base (Guthrie 1982). The subsequent history of human expansion toward the south through an ice-free corridor presents a classic example of interaction with periglacial environments. It is clear that if this corridor was the main access to the Americas, then hunter-gatherers have to wait until significant biotic resources were available to live and circulate in order to reach the North American plains (Meltzer 2009). Alternative coastal routes were proposed to explain the human expansion to the south, but the northern coastal habitats potentially used by the first colonizers were also in part glacial or periglacial. More recent theories suggest an Atlantic crossing with an origin in the European Solutrean (Stanford and Bradley 2011). This scenario also involves periglacial environments.

Key Issues/Current Debates

The evidence related with the human colonization of mountain environments is particularly relevant. The Tibetan plateau was covered by ice c. 50,000 years ago, after which retreat of the ice facilitated the expansion of animal resources into the plateau. It is postulated that c. 30,000 years

ago, humans entered the plateau, but the evidence is not abundant. At site Xiao Qaidam, 3100 masl, there are simple core and flake quartzite tools probably dating to c. 22,000–18,000 BP. At site Chusang, at 4200 masl, hand and footprints impressed on travertine are dated by OSL approximately 21,700–20,600 BP (Aldenderfer and Zhang 2004: 16). Several sites with core and flake tools are typologically assigned to Paleolithic times. Brantingham et al. (2003) proposed that the plateau was populated from the north, with people getting into eastern Qinghai lakes, at 3000–4000 masl, before the advent of the LGM. It is maintained that at that time, humans acquired the physiological adaptations required to live in the high country. Finally, displacement to the high plateau "may have occurred at the onset of LGM conditions, c. 23,000-22,000 B.P." (Aldenderfer and Zhang 2004: 21). Basically, the timing of the colonization necessarily was in synch with the retreat of the ice.

In the Central Andes, there is evidence of early human populations occupying mountain environments slightly before 10,000 BP (Aldenderfer 1997), while at Agua de la Cueva, Mendoza, Argentina, mountain environments begin to be used around 11,000 years ago (García 2003). In both cases, hunter-gatherer adaptations focused on the exploitation of wild camelids were defined. For these and other high altitude sites, the default interpretation is that human occupations are seasonal. However, interpretations of year-round occupations also exist, for example, at Pachamachay Cave, Perú, at c. 4300 masl (Rick 1980). This cave was occupied since the end of the Pleistocene by wild camelid hunters, and Rick suggested that the conditions were adequate for sedentary occupations. Alternative models can be offered for the evidence of Pachamachay, but it is clear that some of the high altitude environments of the Puna of the South Central Andes witnessed the early Holocene process of domestication of camelids (Yacobaccio 2007), a process that at some point was unequivocally related with year-round occupations.

Glacial and periglacial landscapes can be very prohibitive for humans, requiring complex sets of adaptations (Binford 1978). One example is the Paleo-Eskimos that were living in the relatively warm climate of the Arctic mid-Holocene, a region whose climate at some point began to change toward very cold conditions. One result was that entire sectors of that area were abandoned. The availability of both terrestrial and sea mammals was basic to select regions of human survival, which was possible even when it changed dramatically to the point of unpredictability, especially in Arctic Canada (Hoomard 2011). Hunter-gatherers living in the central Arctic were able to adapt to this conditions, probably constituting the best example of a human population living under glacial conditions. Of course, they were continuously exposed to starvation and other risks, especially during the Little Ice Age (McGhee 1997). Except for the mountain habitats, the importance for humans of periglacial environments in the Southern Hemisphere is less notable. Ultima Esperanza, Chile, is one of the few places where early colonizers were regularly living relatively close to the ice near a proglacial lake c. 10,500 years BP (Martin et al. 2011). Moreover, in other Southern Hemisphere places like Australia, there were very few areas affected by glaciers, and it is possible that the distribution of ice played no role in the process of exploration and colonization.

As already mentioned, mountains offered some of the more characteristic human-inhabited periglacial landscapes. For example, the lands around the Andes or the Himalayas present large high altitude periglacial habitats that were inhabited by humans with difficulty. Humans are not adapted to live in high altitude and required behavioral, cultural, and physiological adaptations to those habitats in order to survive (Aldenderfer 1997: 19–25). For that reason, the process of human colonization of these and other mountain environments started near the end of the Pleistocene and only after the effective colonization of lowlands nearby took place.

Future Directions

One problem in understanding the archaeology of periglacial landforms is that glacial erosion and other dynamic processes associated with deglaciation probably erased any indications of previous

human occupation. This is especially important since many proglacial lakes and other areas marginal to glaciers probably functioned as magnets for earlier colonizers, and the catastrophic draining of lakes completely destroyed any sites located nearby. For this reason, formational and taphonomic studies will be crucial in appreciating the magnitude of these problems and in trying to reconstruct the history of human use of those environments.

Finally, the literature discussing the tactics and strategies used by humans living under periglacial conditions emphasizes the availability of fire technologies and all kinds of shelter adaptations (Jochim 1981). Even more important is the existence of a full suite of secondary adaptations, like the intensive use of the different products offered by hunted animals, the use of stone boiling, or the use of bones for fuel. Examples of humans inhabiting periglacial habitats using these and many other tactics are well described in the literature (Jochim 1981; Soffer 1985; Meltzer 2009) and constitute the best proof of human adaptability. Bioanthropological studies should play a more important role in discussing these adaptations in the past, since it was only by conquering periglacial environments that *Homo sapiens* was able to successfully colonize the earth.

Glass Beads from Australian Indigenous Sites

Mirani Litster
Department of Archaeology and Natural History, College of Asia and the Pacific, The Australian National University, Canberra, ACT, Australia

Introduction

The study of glass trade beads from various archaeological contexts, including contact and post-contact sites in North America, has been constructive in both advancing analytical methods and also in understanding past cultural entanglements (Hancock 2013); nonetheless, corresponding finds and reported studies from Australian Indigenous site contexts – such as rock-shelters and middens – are comparatively rare, occurring in reported quantities numbering less than 300 to date, and are largely constrained to western Arnhem Land in the Northern Territory (NT) (Allen et al. 2018; James et al. 2017; Litster et al. 2018; Wesley and Litster 2015a, b; Fig. 1).

This situation contrasts to the many historical references to the trade of glass beads in Australia from 1705 onward. An early source refers to the Dutch vessels the *Vossenboch*, *Nova Hollandia*, and *Wajer*, which explored the Tiwi Islands in the Arafura Sea in 1705, with the locals "... very greedy after linen, knives, beads and such knick-knacks" (Forrest 1995:16). Later references include the observations of the crew of the First Fleet in New South Wales (NSW), who were stocked with "articles of traffick," such as beads (McBryde 2000). Baudin described the appeal of beads in southern Tasmania in 1802 remarking "I had provided myself with a few presents, so I held up some necklaces of sparkling beads, which drew their attention. One of them signalled me to give them to him" (Baudin in Plomley and Piard-Bernier 1993:130). Baudin's botanist Leschenault also described early encounters "...one of the last of this group seemed to have some authority over the others ... he gave me a necklace he was wearing, which was made of small shells of glistening mother-of-pearl, threaded on a small cord made of bark and grass. He asked in exchange a necklace of glass beads" (Plomley and Piard-Bernier 1993:130). Allen et al. (2018) also discuss the significant signing of the "Batman Treaty" in 1835 where the east Kulin nation were given "blankets, scissors, knives, looking glasses, tomahawks, beads and flour in exchange for land around Port Philip Bay in Victoria." Taken together, these examples of the many accounts referring to glass beads suggest that the exchange of these objects was commonplace during the era of contact and thereafter.

Definition

Glass beads are small perforated ornaments manufactured from silica (e.g., quartz or sand), fluxes (e.g., potash, soda, or plant ash), and additional colorants and stabilizers. They are

manufactured through a variety of methods, which includes drawn, wound, wound on drawn, mold pressed, blown, or prosser molded (Karklins 2012:63). Glass beads can be used as suspended ornaments placed on the body or incorporated into other items of material culture, such as bags and clothing. Their durable and portable qualities enable their widespread distribution, which in the past has manifested through exchange, gifting, and, in some instances, use as a currency.

Early "trade" beads include those of the Indo-Pacific type (previously known as "trade wind beads"), which were first manufactured at the entrepôt of Arikamedu in India from approximately the third to second century BC and have been found in contexts ranging from Africa through to Japan (Katsuhiko and Gupta 2000). Later, European "trade beads" were manufactured in production centers in Bohemia (now Czechia), Venice, France, and the Netherlands. Trade beads were widely dispersed by the Spanish, Dutch, French, and English in exchange for services and commodities (including slaves) and were introduced into the Americas and Western Africa in the fifteenth century. In Australia "trade beads" have also been referred to as "contact beads" in order to avoid the assumption that they were only traded, as they may have been gifted or purchased (Allen et al. 2018; Wesley and Litster 2015a; see Fig. 2 for examples found in Australian archaeological contexts).

Historical Background

Australian archaeology has long emphasized questions concerning the early arrival of people to Australia (Clarkson et al. 2017), and consequently, "contact" and "post-contact" archaeologies, along with the associated study of artifacts such as glass beads, have received less attention (Harrison 2005). Early "contact" research was initiated in the late 1960s, with Allen's (1969) doctoral research on the nineteenth century Port Essington settlement (see Fig. 1 for location). Macknight (1969) also investigated Macassan (the mariners originating from Sulawesi who travelled to Australia to exploit the natural stocks of trepang) engagements in northern Australia. Birmingham (1976) later reported on several

early-to-mid-nineteenth century sites, including the "pottery enterprise" of settler James King in New South Wales, the Wybalenna mission on Flinders Island, and the Hill End gold rush town in New South Wales. During the 1990s scholars advanced a new phase of contact research, with theoretical progress made by Murray (1993), who presented the concept of "the historical archaeology of Aboriginal Australia." This diverted discussions away from unidirectional acculturation models that were prevalent in contact archaeology (Harrison 2005). In the 2000s, studies preferenced the terms "engagement" and "entanglement" over "contact," promoting the agency of "Indigenous participants in cross-cultural meetings" (Harrison 2005). It is against this backdrop that archaeological research into glass beads has been undertaken.

Glass beads have been reported from a range of contact and post-contact sites, including Wybalenna mission (Birmingham 1976) and Ooldea Soak and mission in South Australia (Brockwell et al. 1989). Blue glass beads were reported from a burial from Snaggy Bend on the central Murray River (Clark and Hope 1985). One blue glass bead was reported from Curracurrang Rockshelter, in northern New South Wales (Megaw 1969). In the Northern Territory, Macknight (1969) reported glass beads found at Anuru Bay, Schrire (1982) reported beads from Jimeri I and Jimeri II, and Mitchell (1994) reported on clay beads from the Cobourg Peninsula, with Clarke (1994) reporting on glass beads from Groote Eylandt and Bickerton Island. More recently, Wesley and Litster (2015a, b) have produced dedicated studies on the glass beads from the Wellington Range and at Minjnymirnjdawabu (Litster et al. 2018; Fig. 1), with James et al. (2017) also describing a single find from Dalakngalarr 1.

Key Issues/Current Debates

One main issue surrounding the study of glass beads in Australian sites – in particular northwestern Arnhem Land sites – relates to the source and the timing of exchange. Wesley and Litster (2015a) proposed a model for the introduction of glass beads in northwestern Arnhem Land, suggesting that they were initially introduced via Macassans in the eighteenth century (or beforehand), with subsequent introductions occurring via various vectors including Europeans and also possibly Japanese pearlers (Wesley and Litster 2015b). This model for a Macassan introduction is supported by other glass bead finds (Clarke 1994) and the presence of Makassarese words in local Arnhem Land languages, including the terms *manik-manik* (bead) and *ammanimani* (necklace) (Evans 1992:76).

Further hypotheses have been developed on the function of beads within customary systems. Wesley and Litster (2015a, b) suggest that they were incorporated into a hybrid economy functioning between Indigenous communities, Macassans and Europeans (Altman 2005), likely representing the "individual expression of customary rights in negotiating with Macassans and European economies" (Wesley and Litster 2015a). Importantly the archaeological sites of Maliwawa and Minjnymirnjdawabu (Red Lily Lagoon) in the NT (see Fig. 1) returned bead splatters/drips from excavations. Drips and splatters are refuse products of bead production and are contained in packages of beads (Fig. 3). These splatters indicate that beads were arriving at these sites unstrung, highlighting the potential for beadwork possibly occurring at these locations (Wesley and Litster 2015a).

Methodological concerns have also been raised by researchers (Litster et al. 2018). Firstly,

Glass Beads from Australian Indigenous Sites, Fig. 3 Examples of glass drips and splatters (RL 72 from Minjnymirnjdawabu and WR18 from Maliwawa). (With thanks to the Manganowal Traditional Owners, the Manilakarr Clan, and Daryl Wesley. Photo: Mirani Litster, with a Zeiss 2000-C stereomicroscope and an AxioCam MRc5)

most of the glass beads from archaeological sites derive from either undated contexts or are dated by association. This is problematic, as much like seeds, beads readily move in deposits (Wesley and Litster 2015a). Another major methodological issue is associated with current fieldwork methods often adhered to in Australia. As illustrated in Litster et al. (2018), the sieve sizes required to capture glass beads include those with screens ranging from 1 to 3 mm (preferably 1 mm); however larger sieve sizes are commonly used. This situation has probably contributed to the low numbers of glass beads recovered in Australian archaeological contexts. Similarly the "telephone box" excavations often seen in Australia, involving small quantities of 1 × 1 m square test pits, have resulted in a lack of information concerning intra-site spatial dynamics.

Finally, several attitudes toward the study of glass beads have also likely contributed to the marginalization of glass bead studies in Australian archaeological research. Sciama (2001:13) remarked that beads are often considered "trinkets," underlining European attitudes toward what is often associated with feminine work, thus trivializing the significance of these finds in archaeology. Byrne (1996) also identified a resistance to understanding the more recent past, with deep antiquity being correlated (wrongly) with "authentic Aboriginality." Consequently, glass beads have been on the periphery, with studies of objects perceived to be more "authentic," such as organic beads and stone artifacts, receiving more attention.

International Perspectives

Glass bead studies in other regions are well developed. Researchers have adopted both classification systems for recording the physical attributes of beads, in conjunction with studies into the chemical composition of glass bead finds. Early classification systems included the seminal *Classification and Nomenclature of Beads and Pendants*, which was established by Horace Beck in 1928. The most widely accepted was by Kenneth and Martha Kidd's *A Classification System for Glass Beads for the Use of Field Archaeologists* (1970). Most classification systems used today build on these previous systems, especially Kidd and Kidd (1970), with beads typically defined by manufacture method (Karklins 2012:63).

In the 1990s chemical characterization became more routine in bead studies. Importantly, chemical signatures can be associated with "geocultural traditions" (Pion and Gratuze 2016). A variety of techniques and methods have been adopted to better understand the composition of glass beads, including X-ray-based methods, neutron activation analysis, and laser ablation inductively coupled plasma mass spectrometry methods among others. Such approaches have been adopted across a wide range of regions, including in South Africa (e.g., Robertshaw et al. 2010), South Asia (e.g., Abraham 2016), Southeast Asia (e.g., Carter 2016; Lankton and Dussubieux 2013), North America (e.g., Hancock 2013), and Europe (e.g., Neri et al. 2018), which have resulted in more robust temporally sensitive bead sequences.

Future Directions

Because of the focus on "chasing the Pleistocene," contact archaeology and post-contact archaeology have been less emphasized in Australia. This has resulted in a lack of advancement in methodologies and theories about glass beads from Indigenous site contexts. While historical archaeologists have adopted bead classification systems, based on Kidd and Kidd (1970), the chemical characterization of glass beads found in Australia has only recently been applied, although not on archaeological assemblages but on chokers and necklaces housed at Museums Victoria (Allen et al. 2018). Further employment of these combined analytical approaches will result in a temporally and spatially sensitive bead sequence for Australia that has much benefitted international research. As outlined previously the refinement of field techniques will also result in a greater capture of glass beads in sieve residues, which will have significant implications in understanding their continent-wide distribution.

Furthermore, if sampling strategies are modified accordingly, an increased understanding of intra-site bead use might result.

Other identified issues – especially in understanding both the introduction and function of glass beads within customary contexts – will benefit mostly from engagement with other disciplines and Indigenous communities. For example, recent research developed by anthropologist and bead worker Gretchen Stolte has significantly explored the construction of beaded material culture found in collecting institutions (see Anthropology section of Litster et al. 2018 by Stolte), which when combined with oral histories, archaeological data, and community engagement will provide us with greater insight into the social context of these objects.

Glass: Conservation and Preservation

Suzanne Davis[2] and Claudia Chemello[1,2]
[1]Terra Mare Conservation LLC, Charleston, SC, USA
[2]The Kelsey Museum of Archaeology, University of Michigan, Ann Arbor, MI, USA

Introduction

Glass artifacts that are successfully recovered and preserved have the potential to contribute to the archaeological record in many ways. However, conservation and preservation of archaeological glass can be challenging. Some glasses are inherently less stable than others, and some burial environments more deleterious. Surface weathering on archaeological glass is common, and it is rare for glass to survive burial unbroken.

A successful preservation plan for glass incorporates both active and preventive conservation and begins before excavation. Because glass is fragile, careful handling, both at the time of excavation and subsequently, is important for its preservation. Once a glass artifact has been excavated, the level of deterioration, physical damage, and the stability of the glass itself must be evaluated, and steps to improve the artifact's condition should be taken if necessary. Wet or damp glass that may have absorbed soluble salts must be treated to remove the salts and slowly dried. Reconstruction and/or consolidation are sometimes necessary for the study, interpretation, publication, and preservation of archaeological glass, but conservation treatment should be as minimal as possible. Conservation treatment can have unintended long-term consequences, even when the most current recommendations are followed, and should only be undertaken by a conservator experienced in the treatment of archaeological glass. Finally, good storage conditions are required to ensure long-term preservation of glass and are best planned before excavation begins.

Definition

Conservation and preservation for archaeological glass may refer to both active and preventive conservation measures. The goal of active conservation treatment is to stop or slow the rate of deterioration in glass. Cleaning, reconstruction, and restoration, also considered active conservation, may also be involved if these steps are desired for interpretation or exhibition of glass objects. Preventive conservation refers to measures which do not intervene chemically or physically to alter the condition of an artifact, but which act to promote long-term preservation. Careful handling and climate-controlled storage at low relative humidity, for example, are two preventive conservation measures for glass. Preventive conservation is often the most cost-effective means of ensuring long-term preservation for archaeological objects.

Key Issues/Current Debates/Future Directions/Examples

Basic knowledge of the properties of glass is necessary to understand how it deteriorates in archaeological contexts and to plan adequately for its conservation. An in-depth explanation of the chemical composition and physical structure of glass is outside the scope of this entry, but these topics are covered in detail in monographs on glass conservation as well as in many other sources (Davison 2003; Koob 2006). In short, glass is composed of silica, an alkali like soda or potash, and a stabilizer like lime. In wet or damp burial environments, water leaches the alkali from the surface of the glass, leaving behind an unstable layer of silica. This layer will reflect and transmit light differently from the original glass. Depending on the level of deterioration, the glass surface may appear iridescent or opalescent but still relatively intact, or it may appear as if it has a thick, flaky weathering crust, a result of accumulated layers of thin, unstable silica.

Other factors which affect the preservation of archaeological glass are the pH and temperature of the burial environment. The preservation of archaeological glass is dependent not only on the burial conditions – dry environments promote preservation while damp environments accelerate deterioration – but also on the composition of the glass. Glasses made with an organic alkali like potash are inherently less stable. Preservation of archaeological glass not only varies widely from site to site but can also vary across a site, and even on the same vessel.

Deteriorated archaeological glass can be very fragile, and even well-preserved glass is easily subject to breakage. Careful handling is important at the time of excavation to ensure successful recovery. Like other fragile materials, deteriorated glass artifacts can be block-lifted and micro-excavated. Block lifting can assist not only with preserving fragile glass but also with the retention and orientation of the fragments and, therefore, the subsequent reconstruction of complex broken vessels. As with most archaeological materials, rapid changes in the ambient environment should be avoided. Wet glass should be dried slowly, for

example. For the same reason, damp glass should not be tightly sealed in plastic bags or condensation may accumulate on the surface.

The recovery and conservation of glass from very wet or underwater environments, whether marine or freshwater, can be especially challenging. Glass from such environments can be severely compromised structurally, with a consistency like gelatin, and may be permeated with soluble salts. In these cases, a conservator with experience in the treatment of glass from wet environments should be consulted. A few books and multiple articles provide information on conservation of glass from such environments and can be consulted for further information (Pearson 1987; Singley 1988; Hamilton 1996; Anastassiades and Ellis 2008; Mardikian and Girard 2010).

The condition of glass artifacts should be thoroughly documented after excavation, both in writing and with photography. Professional conservators should be familiar with this type of documentation, and archaeologists should expect the conservator to provide a written report summarizing the condition of the artifact(s) and any conservation treatment undertaken. Books on glass conservation can provide more information for those unfamiliar with documenting and describing the condition of archaeological glass (Davison 2003; Koob 2006).

Conservation treatment of deteriorated archaeological glass can be complex. In general, it is a good idea to remove soil and other surface accretions which might attract and hold moisture against the surface. Glass that is not weathered can be gently brushed or even rinsed with water. But if, as is the case with most archaeological glass, the surface is fragile, cleaning can be a dangerous operation and is best left to an experienced conservator. The outer, fragile, weathered layers of deteriorated glass should never be removed during cleaning; they represent the original surface of the glass. Surface details and decoration may be lost if these layers are removed, and the glass revealed beneath them is likely to be dull, pitted, and unattractive.

If the weathered surface of an archaeological glass object is flaky, consolidation of the outer layers of glass may be necessary. The decision to consolidate should not be undertaken lightly; consolidation of archaeological glass is rarely reversible, and the materials used can have long-term effects on the stability and appearance of the object. If the artifact can be stored safely and extensive handling is not required, consolidation of the surface should be avoided. Consolidation should only be carried out by an experienced conservator. Conservation science is a field which advances rapidly, and the most recent literature should be consulted before a consolidant and application method are chosen.

Often, reconstruction is required before fragmentary glass artifacts can be studied, photographed, or drawn for publication. Epoxy resins have been used extensively as adhesives for glass, but they are not recommended for archaeological glass; the epoxies commonly used in glass conservation are too strong for archaeological glass. Their use can create joins which are stronger than the surrounding glass, producing unintentional but problematic strains in joined artifacts (Koob 2006: 48). Softer solvent-based acrylic resins are a better choice, and the use of such resins has been documented and discussed extensively in conservation literature (Koob 1986, 2000, 2006; Horie 2000). The same considerations are important when creating infills for missing areas on archaeological glass vessels. Commonly cited drawbacks to using acrylic resins as adhesives and fill materials are that they must be prepared for use and that they create visible joins in glass objects. There is some truth to both observations, but most archaeological conservators find that acrylic resins are straightforward to prepare and apply, even in field conditions. Invisible joins, desirable in some museum settings, are rarely a concern for deteriorated archaeological glass. A desire to match the refractive index of the glass and a desire to produce joins without small bubbles from solvent evaporation are two reasons that museum conservators might choose an epoxy adhesive over an acrylic resin for joining or infilling non-archaeological glass. However, epoxies do not provide a good refractive index match for most archaeological glass. The small bubbles which result from solvent evaporation in acrylic resin

adhesives, if visible at all, are a small price to pay for an adhesive that will not cause further damage to the glass (Koob 2006: 48–50).

The previous paragraphs have discussed recovery and active conservation treatment for archaeological glass, but preventive conservation following excavation is the most important long-term preservation factor for glass artifacts. A good ambient storage environment is crucial because unstable glass that is exposed to high relative humidity can deteriorate quickly. In general, lower relative humidity is best for storage of glass. Storage at 45% relative humidity, +/− 5%, is recommended for stable glass, and 40% is suggested for unstable glass (Koob 2006: 141). Archaeological glass in storage should be checked regularly for signs of deterioration, which might appear as clouding of the surface, flaking or cracking, or moisture on the surface of the glass.

Glass, although durable, is also easily broken and chipped. It should always be handled and packed carefully. Glass that has adhesive joins and/or fills should be handled with special care, especially if the adhesive is old. Use common sense when packing glass for storage. Glass objects should be well supported, should not be stacked on top of one another, and should not move when drawers or cabinets are opened. Very fragile objects may require individual boxes or rigid containers, but air should be able to circulate around objects and they should not be tightly sealed inside containers, as this can create a microclimate which may accelerate deterioration of unstable glass. Acid-free storage materials are best (i.e., not wood or acidic papers like newsprint). A good, soft packing material is unbuffered acid-free tissue paper. Place the heaviest part of any object towards the bottom of the container and provide adequate padding. Inert foam, like Ethafoam, can be used when sturdier support is required.

When packing glass for transport, follow the same general principles. Air circulation is less important for temporary situations like transportation. For transport, glass can be completely wrapped in acid-free tissue and even surrounded by bubble wrap. The bottom and sides of the container should be well padded with several inches of foam, and all space between objects should be padded with a material that will not shift when the container is moved. Styrofoam pellets or other types of packing peanuts are not recommended because they may shift during transport and thus fail to provide adequate support (Koob 2006: 141–150).

In conclusion, the conservation and care of archaeological glass is not always straightforward. Glass is subject to damage and deterioration from many sources, and each artifact, collection, and site will present unique challenges. Collaborative planning that involves both archaeologists and conservators will yield the best results when designing conservation treatment and long-term preservation plans for archaeological glass.

Basic Biographical Information

Internationally known folklore scholar Henry H. Glassie III, born March 24, 1941, received his B.A. in English and Anthropology from Tulane University (1964), an M.A. in Folk Culture from the Cooperstown Graduate Program of the State University of New York at Oneonta (1965), and a doctorate in Folklore from the University of Pennsylvania (1969). During the period of his doctoral work, he was the State Folklorist of Pennsylvania and Director of the Ethnic Culture Survey (1967–1969) for the Pennsylvania Historical and Museum Commission. He taught at Indiana University's Folklore Institute (1970–1976) before returning to Penn as Chairman of the Department of Folklore and Folklife (1976–1988) and coming back to Indiana as College Professor of Folklore (1988–2009). Glassie also served as Codirector of Turkish Studies and held adjunct appointments in Central Eurasian Studies, Near Eastern Languages and Cultures, and American Studies, and is now Emeritus Professor, Department of Folklore and Ethnomusicology and Emeritus Adjunct Professor, Department of Near Eastern Languages and Cultures. He also helped establish three museums in the United States and Ireland, including Conner Prairie, an outdoor living history museum in Fishers, Indiana. He is married to Pravina Shukla, a folklorist who specializes in clothing and adornment; they have four sons and four grandchildren.

Major Accomplishments

Glassie was a John Guggenheim Memorial Foundation Fellow (1972) and an Invited Fellow at the National Humanities Institute (1975–1976). In addition, he was a Fellow of the American Folklore Society (1976) and served as its president (1988–1990); he was also president of the Vernacular Architecture Forum (1983–1985) and Senior Research Associate at the Museum of International Folk Art (1986–1993 and 1993–2000). During the 1990s, Glassie was honored as a Folklore Fellow of the Finnish Academy and received an Award for Superior Service by the Turkish Ministry of Culture and the Award for Outstanding Achievement in the Arts by the Assembly of Turkish American Associations, as well as a Certificate of Honour from the Ministry of Cultural Affairs of Bangladesh. In 2003, the Vernacular Architecture Forum honored him by naming its outstanding achievement accolade the Henry

Charles C. Kolb has retired.

Glassie Award. With expertise in folk art, folklife, vernacular architecture, and material culture, Glassie has written 24 books and 102 articles on folklore and material culture from Ireland, Turkey, Bangladesh, and the United States (especially rural Virginia) (1999a, b, 2000a). Most books are illustrated with Glassie's own photographs and drawings; he also designed many of the Indiana University Press's volumes. His initial research resulted in major books on vernacular architecture (1969, 1975), followed by five books about Irish culture. In 1982 he began studies on the living arts of modern Turkey which resulted in a major traveling exhibition and book (1993), with additional research in South Asia (1997, 2000b), and a biography of a Nigerian artist (2010). Recognized as a master teacher at Indiana, he has received the Teaching Excellence Award from Indiana University. In 2000 he was named by President Clinton to serve on the National Council on the Humanities. Three books have been named by *The New York Times* as "Notable Books of the Year"; *Vernacular Architecture* (2000a) was the winner of the 2001 Cummings Award for the best book on North American architecture. Glassie is presently working on a monograph on Japanese figurative ceramics.

Introduction

The history of science cannot be dissociated from its multiple contexts (Patterson 2001), whether they be in the physical or the spiritual domain. To

tackle the topic of the rise of global archaeology, we choose to reflect on three great ruptures in the experiential context of the history of western humanity and consequently of the human sciences.

The first of these is linked to the very concept of culture. If before the end of World War it were possible to imagine a homogenous culture, pure or superior, after the experiences of the totalitarian states (Arendt 2004: 3–15), the danger of thinking about culture in the singular became evident. The effect of the tragedies caused by Nazi-fascism, added to the later experiences of the different civil rights movements, was to introduce pluralist aspects into culture, including the humanistic and therefore the global. In this new context, the Declaration of Human Rights, among other things, gathered strength and was adopted by the United Nations Organization on December 10, 1948. Apart from the many criticisms that can be made, this Declaration did consolidate the idea of the universality of basic human rights.

The second rupture, closely related to the former, is centered on the human conception of the environment in which we live. The premise arose that all our actions have global consequences, based on experiences with nuclear weapons and the uncontrolled use of agro-toxins, both of which saw the rise of epidemics and disease. With the ecological movement was born the premise that it is imperative to think globally and act locally.

Finally, the third rupture was linked to the end of the Cold War and the fall of the Berlin Wall. By the mid-1980s, capitalism was accepted as the choice for life; it seemed to have been victorious, and in turn it became plausible to consider a history of mankind from the ideological bias of capitalism.

Clearly one could have chosen other ruptures to contextualize the birth of global archaeology, but we consider that these three lines will help us to understand the globalization process and the expansion of thinking about humanity. The influence of this thinking about human beings in a global context can be seen in various fields of knowledge, one of which is archaeology. It is quite common to find in the discussion agendas of this discipline, such as in the World Archaeological Congress (WAC), proposed topics related to the "re-humanization" of archaeology and global archaeology. Our aim is to understand some of the ideas that support these proposals.

Definition

Archaeology as a discipline started in the nineteenth century in the wake of the main thrusts of globalization, such as the spreading of capitalism worldwide and the imperial moves by colonial powers. The main intellectual ambitions of the discipline were also global, such as understanding the spread of material culture over large areas and later in the century the evolution of human ancestors (Boast 2009). In the twentieth century, this trend grew even larger, as witnesses the ambitious project of a global archaeological understanding of the whole human past as proposed by Vere Gordon Childe (1951). However, archaeology as a global interpretive move was very much centered on a core of western scholars and institutions, so that even the most daring global perspectives, such as Childe's, took a patronizing approach, leaving peoples and civilizations of the past as predecessors to the enlightened western world. So, culture history (Webster 2008: 34) and a global discipline did not escape the traps of being part of the array of western domination of the world.

The situation changed dramatically though in the later part of the twentieth century due to several reasons, not least the emergence of a plethora of social agents: women established themselves in the workplace and public sphere; former colonized peoples fought for their liberation; ethnic, religious, and other minorities struggled to have their rights recognized; and sexual liberation also led to new social mores in both western and non-western countries. Archaeology would not remain for a long time isolated from all those social changes, for, as David Clarke proposed as early as 1973, it lost the innocence (Clarke 1973). The Paradise Lost – echoing both Genesis, chapter 3, and Milton's opus magnum – was this land of joy but no awareness about the limits of knowledge itself. Processualism was a first response (Watson 2008: 2), soon to be criticized from several quarters (Johnson 2009). The emergence of social actors – women, blacks, and former colonized

peoples and beyond – led to a challenge to the old global approach and fostered a new, less imbalanced global archaeology. The World Archaeological Congress (Ucko 1987: 10), established in 1986, has proven a turning point in this new direction, for two different but related reasons (Funari 2006).

In epistemological terms, diversity, pluralism, and conflict in interpretation were increasingly recognized as key concepts to interpret the archaeological record, considering how important those same tenets are for contemporary life. This is directly related to a global approach to knowledge, considering that different people, in different historical and cultural contexts, offer a diverse array of understandings of the world and of material culture, as a consequence. The African origin of all human beings is seen probably from diverse perspectives in Africa and in other continents, and the role of chinaware is perceived also probably differently in China and in other parts of the world, to mention just two subjects clearly related to global issues. Archaeology shifted from a potentially limited, western narrative of the past to a chaotic, but pluralist, study of past material culture, from a variety of conflicting standpoints. This is indeed a huge epistemological shift from a normative, uniform, and totalizing narrative to a diversity of different interpretations. As Nick Shepherd (2005: 26–30) put it, this was a move from one world archaeology to one world and many archaeologies.

In social terms, all those concepts were related to the inclusion of a variety of social actors in the scholarly field of archaeology, in a global scale. Archaeologists from non-western countries were often sidelined or ignored and considered as part of the uncivilized scholarly world. This changed gradually and WAC was a major turning point. The new scholarly association for the first time ever was run by a worldwide body of scholars and included also native representatives, traditionally subjects, not actors in the scholarly world. Western scholars were for the first time in a minority and global gained a new meaning, really implying the participation of archaeologists from all over the world. Then, breaking with hierarchical tenets, WAC put together senior scholars and young students, and also natives and other social actors, so that a major hierarchical principle of western scholarship was put down (Smith 2005: 20). This is also a new global approach, taking global to mean comprehensive. So that epistemology and social aspects are interwoven in inextricable ways.

A global approach has also been related to capitalism, as pointed out by Michael Shanks (2008: 142): "Some have discerned a latest cultural phase, belonging with postmodernity and termed globalism. It refers to the expansion, especially after the fall of the eastern bloc in 1989 and after, and with the opening up of communist China to market forces, of the capitalist market across the globe." It is indeed impossible to set apart capitalism and globalization, so much so that historical archaeologist Charles E. Orser (1996) equated modernity, globalization, and capitalism and established the starting point as early as 1415. It is also clear that globalization did not end local specificities and, to the contrary, contributed to a plethora of global and local interactions, encouraging local identities and standpoints, as stressed by Wallace (2008: 12–18):

> The internet's ties to globalism are clear-cut. Yet the goals of the Internet highway's profiteers to "promote a world culture" (Bill Gates) conversely contribute to the desire by many people do find their own personal or group's identity within this global world. In fact, globalization is just a continuing process, which started much earlier and archaeology is particularly apt to deal with the subject (Kristiansen 2009: 36). Global archaeology in this sense is a catch word for archaeology in contemporary context, and it is no longer possible to think specificities without references to overall processes (and vice-versa).

Key Issues/Current Debates

Towards Global Thinking: Transformations of the Concept of Culture

Through the twentieth century, it is easy to find historical events that serve as models for understanding the conceptualization of past, present, and future (La Capra 2001). Undoubtedly, among these examples, we can highlight the

experiences of two world wars and their accompanying genocides, the civil rights movements, and feminism, which have all generated a new reflection on culture, memory and politics, and other topics related to constructing a present that is more democratic and diverse.

Specifically in the case of culture studies, which appear in the Humanitarian Sciences of Archaeology, Anthropology, and History, among others, the aforementioned events had a wide impact in the 1950s. According to the cultural theorist Stuart Hall (1980), three publications were fundamental to the interior revolution of this investigative field: firstly, *The Uses of Literacy: Aspects of Working Class Life*, published in 1957 by British author Richard Hoggart; secondly, *Culture and Society*, published in 1958 by the Welshman Raymond Williams; and finally, *The Making of the English Working Class*, published in 1963, by E. P. Thompson.

Despite marked epistemological differences between the works of Hoggart,Williams,and Thompson,which nonetheless came from each of them reading Karl Marx, the three intellectuals brought drastic changes to the way "culture" was treated. According to Hall, the change was linked to new ways of conceiving society, given that until this time "culture" had been viewed as the "anniversary calendar" of social display, that is to say, as demonstrations barely to be considered a product of economic status; after the publication of these three works, culture came to be viewed as the pillar of society. So culture became the primary concern of the humanities and was no longer seen as superfluous to economic and political topics.

According to Hall, these intellectuals tried to draw their readers' attention to the idea that the concept of culture includes matters directly related to the so-called great historical changes (Hall 2009: 127). However, it was Raymond Williams from among the cited authors who chose to open dialogue with archaeology, thus moving towards building a global perspective.

From among Williams' many definitions of culture, two caught the attention of Stuart Hall. The first related culture to the sum of possible descriptions by which societies bestow meaning on the world and reflect on their common experiences (Hall 2009: 126). Thus intellectual history was not only concerned with those few western traditions classified as "worthy of record," such as the great artists of the Renaissance, the great monuments and construction works of Antiquity, or the writers of holy illuminated texts. On the contrary, it dealt with the idea of a democratized "culture" that encompasses any human being's descriptions of the world.

While this first definition developed the concept of culture as an idea, the second definition would take in the anthropological universe. On this occasion, Williams emphasized culture as related to social practices and characterized culture as a global way of life (Hall 2009: 126). According to Hall, by integrating diverse lifestyles, this definition became one of the central axes of humanities.

From this viewpoint, the theory of culture became defined as the study of the relationships between typical elements of a global lifestyle. So culture would be neither a practice nor the descriptive sum of a society's popular customs. On the contrary, it would overflow the confines of social practices to become the sum of the interrelations that exist between them.

The writings of Raymond Williams were of added importance to the birth of new fields of action in the archaeological field. In the British case in particular, according to archaeologist Paul Courtney (2007: 38), landscape studies and the later foundations of industrial archaeology were profoundly influenced by Williams' text, *Culture and Society*. In understanding the relationships between human groups, having the starting point as an analysis of the cultural material was one contribution that would have made archaeology a new point of reference.

This new field, built from discussions of Hoggart, Williams, and Thompson, would be institutionalized in the 1970s as the "Linguistic Turn" Movement. The Linguistic Turn, whose roots lie, in part, within anthropology, immediately influenced the definition of culture as well as its supposed global character.

In 1973, the US anthropologist Clifford Geertz published *The Interpretation of Cultures: Selected*

Essays. Profoundly disturbed by the so-called conceptual bog around culture – which, according to the author, ended up creating an indefinition of the term – Geertz applied himself to building his own redefinition of culture and of all the areas involved in cultural studies. For Geertz, culture would always be something essentially semiotic. In his own words: "Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be not an experimental science in search of law but an interpretative one in search of meaning" (Geertz 1973: 5). From this point of view, all science dedicated to cultural analysis would be, therefore, interpretive science.

Supported by his interpretation of the "thick description" of English philosopher Gilbert Ryle, Geertz championed the practice of ethnography as a field that deciphers codes, and chooses and reads semantic structures, attributing to them specific meanings. This means that cultural interpretation would become an incomplete and subjective operation, since it is characterized by the understanding of human behavior as a symbolic action. For the readers – and followers – of Geertz's proposals, his description of the actions, possibilities, and limitations of ethnography act as a window through which human sciences can be understood as a whole, across the fields of anthropology and archaeology and including historiography.

Beyond this concept of culture, which is related to the beginning of contextual archaeology (Hodder 1982), we are also interested in understanding the limits Geertz imposes on the work of cultural reading. According to the anthropologist, there are three characteristics of ethnographic description: it would always be interpretative, it would interpret the flow of social discourse, and it would aim to save the "said" through speech in forms that are able to be investigated. Finally, he adds one more: the reading is microscopic. This is where we meet the problem of thinking on a global scale.

According to this theoretical model, culture is understood contextually; in this way, it can only be read on a singular and small scale: the local dimension. For Geertz, the only global element of the semiotic model for the interpretation of culture is that which allows us access to the conceptual world with which our subjects overlap, in such a way that, with this wider scope of meaning, we would be able to communicate (1973: 35). In this way, the global nature of thought would respond better to our desire to establish general rules of human behavior than would the possibility of understanding its local specificities. Not because the global should be left aside; on the other hand, for this author, whatever generalization we manage to establish should come from the finesse of its particularities and not from the scale of its abstractions. Thus, the local scale is shaped as a crucial piece of any attempt to think in global terms.

Geertz's proposals, which were explored and amplified through the studies of anthropologists from the School of Chicago in the 1970s, had a significant impact on anthropology and archaeology, upsetting the existing trend among behaviorists, linguistic formalists, and the like. The proposal of the symbolic interpretation of cultures on a local scale, cultures which nonetheless showed global interconnections, would gather strength within the humanities area.

In the particular case of archaeology, one cannot deny the contribution to the forms of analysis on a global scale of North American anthropologist James Deetz and his work *In Small Things Forgotten*: *The Archeology of Early American Life*, dated 1977. For this author, archaeology has a duty to approach anthropology with the aim of comprehending the diffusion of European culture around the world, commencing in the fifteenth century, and from this perspective understanding the impact and interactions between those cultures that were expanding and the native cultures they affected. Understanding of the so-called global transformations was modeled on an analysis of the small actions (and objects!) of daily life, many of which were related to food and housing in the North American colonies. In this way, the global scale was built up from the analysis of highly specific contexts.

For Deetz, who dialogued with anthropologists Edward Burnett Tylor, Franz Boas, Alfred L. Kroeber, Leslie White, and Claude Levi-Strauss,

the concept of culture should be the central paradigm for the conception of archaeology itself. Supported by the studies of Walter Taylor (1948: 50–64), culture was defined in this context as mental constructs that cannot be observed directly, but rather come to light in different ways, such as ritual practices, social structures, and even the physical world. Global scale thinking became part of archaeology, in the beginning from discussions of the term "culture" and consequently from debates about how each researcher perceives the world they are studying. Speculations in the theoretical area were closely tied to archaeological practice.

Global Thinking: The Ecological Movement on a Global Scale

Change to the concept of culture, as well as the consequent value given to the global scale, was intertwined with the gradual understanding of the "environmental crisis" in the second half of the 1950s (Palacio 2002: 13). Concomitant with an increased value given to a new model of life based on consumption, a practice stimulated by the world of the Cold War was the beginning of doubts about the same model. During the decade of the 1950s, pollution of European rivers, for example, the River Thames, reached alarming levels, while air contamination produced a proliferation of severe respiratory problems in the population. Even the seemingly unquestionable models of food production were put in check by the book *Silent Spring* (1962) by Rachel Carson.

In this book, the author denounces the chemical products used to improve agricultural production. From the 1950s, then, people were casting doubt on the belief that technology and science were the saviors of humanity. The perception that something had gone awry, something inherent in the development models being practiced in the West, would bring about the correction and redefinition of the concept of "environment" and in the same way expand its field of action to a global scale.

If the concept of the environment had previously been relegated to the darkest corners of scientific theory, by the 1960s, it became the banner of social movements, besides movements for the defense of civil rights and feminism. From then on, the definitions of what is "environment" have multiplied. In 1969, for example, the British researcher James E. Lovelock, with the North American biologist Lynn Margulis, launched the "Theory of Gaia," which imagines the planet Earth as an enormous living entity capable of self-regulation. The Theory of Gaia, which won sympathizers from members of mystic movements, environmentalists, and some researchers, facilitated the popularization of the concept of "environment" as composed of not only natural resources but also of human beings. Within this conception, man forms part of a planetary whole that is able to self-regulate and respond to the aggressions it suffers. The Earth, in this context, can be defined as the interaction between living and nonliving beings.

In his search for a holistic theory of environment, the geographer Yi-Fu Tuan defined "environment," in this same decade, as the set of conditions under which any person or thing lives or develops. The environment would be, therefore, the sum total of the influences that modify the development of life or character (Tuan 1974).

In a more pragmatic way, the environment could also be understood from the viewpoint of natural resources, a trend that materialized in the report *The Limits to Growth*, produced by the Club of Rome and published in 1972. In this report, the sustainability of the planet was analyzed, in terms of the demand for raw materials and natural resources, as well as eventual wastes. In this text, it was affirmed that the planet Earth could not support population growth, owing to the pressure that this would produce on the natural and energy resources and the increase in pollution, when taking into account technological advances.

From the 1960s, therefore, the definitions of "environment" have become different from the concepts of landscape. According to Brazilian researcher Tereza Emidio, the landscape became an integral part of a wider universe, denominated "environment": this landscape could be conceived then as a universe in miniature which, when articulated with other small universes, would constitute the environment (Emidio 2006: 13–4).

In this way, the global scale is converted into an imperative, above all for the biological sciences, which should come around to conceiving human actions as phenomena that cause an impact on the globe, this being conceived as a whole (Kingsland 1985).

Global Capitalism and a New Historical Archaeology

The archaeology of modernity and global capitalism has been particularly focused on a comprehensive approach, but it took a time for this universal stand to develop. Historical archaeology started in the United States as the narrow study of the Anglo-American material culture, excluding African-Americans, Natives, Latinos, Jewish, Irish, Italian, and other components of the American past. Critical understandings started in the 1970s and 1980s, mostly from a Marxist background, with groundbreaking studies by Orser, Leone, and MacGuire (Hicks and Beaudry 2006: 27–30). There has been since then a growing emphasis on global features of modernity, taking capitalism as a force organizing "a set of social relations," as put by Leone in 1999. Orser stressed that there is no global trend without local features, so that global and local are interwoven and enmeshed in profound ways.

From the late 1980s, from a global perspective, several archaeologists questioned the universal role of capitalism and proposed instead a variety of specificities in different continents, countries, and regions (Funari et al. 1999). Diversity and identities in the plural have also featured a plethora of studies, from Shanks and Tilley (1988: 5–10), and Voss (2008: 18–20), but also peripheral outlooks (Funari et al. 2005). Global archaeology did not lose its strength, but recognized the relevance of concrete situations in different historical and social contexts.

Future Directions

Archaeology has moved from a most conservative and even reactionary endeavor to become a force for change in the contemporary world. It is a no mean feat in itself. Within a few two or three generations, the discipline moved from defending the status quo, hierarchical relations, and social imbalances to contributing to challenging all those features and to promoting diversity, freedom, and the empowerment of people in general. There is future for archaeology out of a global perspective and the actual practice in concrete situations (Jones 2009: 109). Archaeologists are now largely from non-western countries, thousands of them from China, India, Japan, and other Asian countries, a large number from the Middle East, Africa, Latin America, Central Asia, and beyond. The USA, Canada, and Western Europe continue to be crucial do the discipline, but archaeologists working there are now in a minority and will increasingly be so. However, most archaeological intellectual scholarship is still from former colonial powers and this is to remain so for quite some time. A global archaeology is an archaeology accepting and including all those mixed features.

Global Heritage Fund (GHF)

Jeff Adams
University of Minnesota, Palo Alto, CA, USA

Basic Information

Global Heritage Fund (GHF) is a private, nonprofit organization dedicated to the preservation of endangered archaeological and architectural heritage sites in developing countries and regions. It is distinguishable from other international heritage preservation nongovernmental organizations by its exclusive developing country focus and its signature methodology integrating conservation and economic development.

Headquartered in Palo Alto, California, GHF was founded in 2002 by entrepreneur Jeff Morgan. Morgan oversaw day-to-day operations as Executive Director, serving under a Board of Trustees responsible for determining overall strategy and direction until 2013, when Dr. Vince Michael took over the post. A Senior Advisory

Board comprised of a multidisciplinary team of noted archaeologists and architectural conservators provides guidance in matters of conservation.

Funding for GHF operations comes from corporate and private donations and project-specific matching allocations from governmental and nongovernmental organizations. According to GHF, they had invested $25 million and garnered $20 million in project co-funding as of 2011 (Jeff Morgan, *pers. comm*. 2011).

GHF seeks to advance the goals of site conservation, community development, and preservation advocacy through a program of field projects, fellowships, the Global Heritage Network (GHN) initiative, and various workshops, events, and publications.

Major Impact

Over its first decade of operations, GHF staged 19 major conservation projects in 12 countries. Project sites are selected on the basis of their estimated significance, threat level, regional economic need, and potential for long-term sustainability via community involvement. GHF has historically focused on World Heritage Tentative List and other major sites informally deemed to possess "Outstanding Universal Value." Of particular interest are those for which preexisting preservation leadership and grassroots support has been in evidence. The GHN threat-monitoring initiative, described below, informs the identification of potential GHF project locations through a program of expert site assessments.

A hallmark of GHF field projects is their overarching focus on long-term community development through heritage tourism, for which the conservation of physical fabric is intended to serve as catalyst. What GHF describes as an "integrated community-based conservation and development" framework is built around a trademarked "Preservation by Design" methodology comprised of four elements: planning and protection, conservation science, community development, and partnerships.

Planning and protection refers to preparatory research and investigation, the development of conservation and master management plans having defined goals, responsibilities, milestones, and provisions for monitoring. Conservation science refers to tailored research and direction by leading international architectural conservators in consultation with local experts. Community development includes local-level promotion, training, and capacity building for conservation, site management, heritage tourism, and craft production. Finally, GHF views partnerships with in-country governmental, academic, and special interest groups for conservation, funding, and executive management to be tactically and strategically critical.

Current and completed GHF projects include work at sites in East, South, and Southeast Asia; the Middle East; North Africa; South America; Central America; and Eastern Europe. These have entailed the conservation of historic structures, at places like Izborsk (Russia) and Pingyao (China); archaeological ruins, such as those of Hampi (India) and Banteay Chhmar (Cambodia); and in situ archaeological remains at locations including Chavin (Peru) and Çatalhöyük (Turkey). In ongoing efforts at the rapidly developing World Heritage Site of Pingyao, China, GHF is working with regional governmental and academic institutions to stem the deterioration and loss of traditional Qing Dynasty courtyard houses and promote locally based heritage tourism through a program of survey, planning, conservation, training, and the promotion of local craft production. At the heavily looted ancient Khmer complex of Banteay Chhmar, GHF has assembled an array of domestic and international partner organizations to develop a site Master Plan, stabilize and conserve key structures, facilitate the preparation of a World Heritage List nomination, and train local residents in conservation and tourism. At the Neolithic settlement of Çatalhöyük, GHF has acted in concert with a range of sponsors and collaborators to enact improvements including a shelter, walkways, and signage; conserve murals;

train locals in conservation and tourism; and assist the Turkish Ministry of Culture in the revision of a site management plan and establishment of a regional Heritage Park.

In 2011, GHF launched Global Heritage Network (GHN), an Internet-based preservation collaboration, advocacy, and threat-monitoring platform. Intended to facilitate international information exchange among working professionals and students, GHN consists of a threatened site database, a member community, and a documentation library. "GHN Sites" is a Google Earth-supported dynamic repository of satellite imagery, spatial data, photos, videos, news items, technical reports, GHF-sponsored site assessments, and other resources relating to the preservation of select developing country sites. The "GHN Community" is an online social network featuring preservation news and user-created discussion groups. The "GHN Library" consists of preservation literature such as management plans, studies, reports, articles, and bibliographies pertaining to heritage conservation, tourism, economics, and related themes. In addition to its active member community, GHN is supported through the voluntary efforts of qualified Site Coordinators and Site Monitors.

Other GHF activities include an annual Preservation Fellowship program supporting international students and scholars in the preservation of developing country sites, workshops and public fora on conservation-related topics, and the production of occasional research reports, white papers, a blog, and a biannual newsletter.

To its advocates, GHF's brand of "venture philanthropy" is a model of grassroots preservation engagement bridging developed and developing countries. The direct effects of GHF's work include the physical conservation, protection, and improvement of a significant number of sites and the enhancement of local-level knowledge and skills regarding conservation and tourism. By bringing together networks of partner organizations, they have promoted intra- and international cooperation and raised the visibility of best practices heritage management and planning. Global Heritage Network provides unprecedented public access to information on developing country heritage site management and hosts a sizable community of active participants.

Among the indirect impacts of GHF's efforts must be counted as yet unquantified economic effects of heritage tourism for households and communities, enriched future personal and professional opportunities for trainees and fellows, increased public awareness of the special vulnerability of developing country heritage, and strengthened appreciation among peer organizations of the importance of financial savvy for NGO efficacy and long-term site sustainability. By advertising their Preservation by Design™ methodology, GHF arguably helps to raise the bar of international heritage management practice, accentuating the need for holistic planning, community commitment, and clear accountability.

Goat: Domestication

François Pompanon
Laboratoire d'Ecologie Alpine, Université Grenoble, Grenoble, France

Basic Species Information

The domestic goat *Capra hircus* (Linnaeus 1758) (Mammalia, Artiodactyla, Bovidae, Caprinae) is a small ruminant herbivore that browses on shrubs and weeds. Females reach puberty between 6 and 12 months and after a mean gestation time of 150 days give birth to a single or twins. On average, the wither's height is 60 cm and the weight 60 kg for a female, but these characteristics strongly vary according to the breed (e.g., for females from 27 kg for an African Pygmy to more than 100 kg for a Boer). Both sexes have a beard and horns in most breeds, and many breeds bear wattles. The 800 million goats distributed all over the world are mainly present in Asia and in the Near East (70% of the worldwide population) and are found in almost all kinds of environments. There are more than 640 breeds, including about 560 traditional breeds/populations adapted to local conditions (Fig. 1) and industrial breeds. The worldwide goat population show a high level of genetic diversity distributed independently of the breeds (Naderi et al. 2007).

Timing and Tracking Domestication

Archaeological (Harris 1961) and genetic (Manceau et al. 1999; Pidancier et al. 2006) data revealed that the goat's wild ancestor is the bezoar, *Capra aegagrus* (Fig. 2). Bezoars are distributed in mountains of the Middle East, from southwestern Turkey to central Afghanistan and southern Pakistan (Fig. 3), mainly in relatively arid habitats such as mixtures of rock outcrops and shrubby thickets or conifer forests (Fig. 2). Goats were among the first farm animals domesticated and rapidly had an important role in the economies of human societies. This is due to several characteristics inherited from its wild ancestor, including flexible feeding habits and the ability to live and breed under coarse conditions (Clutton-Brock 1999) and to be transported over long distances. Goats provide meat, milk, and dung (for fuel) but also hair and skin for clothing, or sinew (for glue or strings) and bones used for making tools and weapons. Since the beginning of domestication, the control of livestock by people released environmental pressures such as those exerted by sexual selection or predation on horn morphology or coat color.

Goat: Domestication, Fig. 3 Simplified scenario of initial goat domestication from the bezoar in the Middle East. The *light brown* area represents the geographic range of the bezoar (*Capra aegagrus*) that may not have changed since the beginning of domestication. The *yellow* and *green* areas represent the approximate areas where herd management took place and where true domestic herds were isolated, respectively. The *stars* give an example of localities with bezoars sharing the same genotype (for a mitochondrial DNA gene) supporting past translocations by man (Naderi et al. 2008). In *red*: archaeological sites giving evidence for local pre-Neolithic goat domestication (see text)

Simultaneously, new selective pressures appeared since farmers instinctively or deliberately favored some characteristics. A general trend differentiating domestics from wilds is changes in skeletal conformation (i.e., mainly a reduction in body size), but traditional breeding led to a diversity of locally adapted phenotypes. The intensity of artificial selection strongly increased with the emergence of the breed concept 200 years ago, resulting in the standardization of morphology (e.g., size, coat color) and performance within well-defined industrial breeds.

The bezoar was among the wild ungulates hunted by hunter-gatherers from the Neolithic in Western Asia. Several tactics of animal use, more or less successful, may have been developed to ensure the transition from hunting to domestication. The control and protection of wild flocks kept in a favored place may have existed besides and/or before the taming and rearing of animals that led to the isolation of true domestic herds (Clutton-Brock 1999). Such archaeological prediction of herd management is coherent with the genetic signature of a past demographic expansion of the bezoars from Central Zagros (Fig. 3), which occurred before the isolation of domestic herds (i.e., time of expansion of Iranian goat populations, Naderi et al. 2008).

This is also consistent with young male-biased culling patterns without body size reduction found in this region (Ganj Dareh, Iran) about 10,000 Before Present (BP), although it has sometimes been interpreted as true domestication (Zeder and Hesse 2000). However, the first domestic herds may not have appeared from controlled populations from Central Zagros, but in a region ranging from Eastern Anatolia to Northern Zagros where the wild populations are genetically closer to the domestics and where there is archaeological evidence for local goat domestication c. 10,500 BP (Nevalı Çori, Turkey). However, the managed bezoars from Central Zagros would have contributed to a small part of the domestic gene pool captured in Northern Zagros/Eastern Anatolia through an early translocation of controlled animals (Fig. 3, Naderi et al. 2008).

Human-mediated long-distance transfers during the phase of herd management or at the early stages of true domestication are archaeologically attested by the presence of wild or feralized goats outside the geographical range of the species (e.g., in Cyprus during the eleventh millennium, Vigne et al. 2011). Such feralized populations are still living in several Mediterranean islands. Animal translocations are consistent with the weak phylogeographic structure of the bezoar over its whole range (Fig. 3), which is very unusual in wild ungulates. The high level of genomic diversity currently observed in goats, similar to that of bezoars, cannot be explained by the domestication of less than 1,300–1,900 ancestral lineages (Naderi et al. 2008).

Thus, the domestication of goats has been a long-term process which initial phase lasted at least several hundred years, over a large area (Western Anatolia/Northern Zagros), involving several hundred to several thousand individuals. Independently, an earlier phase of wild herd management in the Central Zagros did not contribute to the modern goat gene pool except by the transfer of wilds and/or early domestics by people to the area where domestication took place (Fig. 3). After isolation of the first domestic herds, goats diffused from the domestication area to reach Western Europe (c. 7,600 BP in southern France), Eastern Asia (not well documented, probably c. 3,000 BP in China), and Africa (c. 7,400 BP in the Maghreb and later than 4,000 BP in more southern parts). The current mix of genotypes in bezoar populations from the domestication area suggest that the weak genetic structure of modern goats at the worldwide level results more from the initial capture of genotypes from already mixed wild populations than from further transportations of domestics for commercial trade (Naderi et al. 2008). The introgression of wild genomes into the domestic gene pool through hybridization may have also taken place, but its importance and timing are still unknown.

State of Knowledge and Current Debates

The Site

Göbekli Tepe is situated on one of the highest points of the Germuş mountain range at ca. 770 m asl., offering a wide view over the Harran Plain to the south. The mound with a height of about 15 m has a diameter of around 300 m and is characterized by several knolls divided by hollows. It is surrounded by a limestone plateau, which mostly shows no soil cover today and only very scarce vegetation (Knitter et al. 2019). Neolithic traces were first reported

Klaus Schmidt: deceased.

G

during a combined survey by the University of Istanbul and the Oriental Institute and Department of Anthropology at the University of Chicago in the 1960s (Benedict 1980), but the megalithic architecture covered by the mound remained unrecognized until its discovery in 1994 by Klaus Schmidt (2000).

Excavations at Göbekli Tepe commenced in 1995, and meanwhile, the site is best known for its monumental round-oval buildings. Measuring between 10 and 30 m in diameter, these structures are defined by monolithic T-shaped limestone pillars rich in symbolic depictions carved in low and high reliefs (Peters and Schmidt 2004; Schmidt 2000, 2012; Becker et al. 2012). These pillars stand up to 5.5 m in height, are interconnected by walls with benches along the inner wall faces, and are arranged around two even larger central pillars (Figs. 1 and 2). Arms and hands carved on some of the pillars confirm their anthropomorphic status. This interpretation is corroborated by depictions suggesting clothing, e.g., parallel bands decorating the front side of many of the pillars; additionally, the two central pillars in Building D carry low reliefs of pendants, belts, and fox-skin loincloths (Fig. 3). This latter structure is one of altogether eight "special buildings" partially excavated so far at the site (Buildings A–H), though results from ground-penetrating geophysical surveys could point to the presence of further extensive architectural structures (Dietrich et al. 2012). In the partially excavated Buildings C and D, the artificially smoothed bedrock constitutes the floor surface. The two "central" pillars were inserted into podia standing ca. 20–25 cm above the smoothed bedrock. Excavations at Building B came to a halt upon reaching a plaster floor. So far no floors have been reached in Buildings A and H. Building archaeological research suggests that the buildings were roofed (Kurapkat 2015). Based on radiocarbon dates, the earliest stone structures appear at Göbekli Tepe in the second half of the tenth millennium BC (Dietrich et al. 2013). The nature and origin of the sediment deposits excavated from the round-oval buildings is the focus of continued research and essential for clarifying whether the original working hypothesis, i.e., that the filling of the buildings was largely intentional, is correct (Clare et al. 2019).

Göbekli Tepe: Agriculture and Domestication, Fig. 1 Göbekli Tepe, the main excavation area with Buildings A–D. (© DAI, photo N. Becker)

In the first half of the ninth millennium BC, rectangular structures begin to appear at Göbekli Tepe (Fig. 4), though most of the "special buildings," which were functional throughout most of the site occupation, maintained their initial round-oval concept. Comparable architecture elsewhere in the Upper Euphrates Basin suggests that this building phase dates to the Early and Middle PPNB (Schmidt 2012; Kurapkat 2015). T-shaped pillars found in the rectangular structures are up to 2 m in height. Although clearly poorer in imagery, their symbolism is reminiscent of that already found in the round-oval "special buildings" (Schmidt 2012; Kinzel and Clare in press).

Architectural findings indicate that the built environment at Göbekli Tepe was long-lived and that "special buildings" were in use throughout the settlement sequence (Schmidt 2012; Piesker

Göbekli Tepe: Agriculture and Domestication, Fig. 2 Building D is the best preserved of the monumental circular buildings of Göbekli Tepe. (© DAI, photo N. Becker)

2014; Kurapkat 2015; Clare et al. 2019). The rectangular buildings have complex biographies as well, with phases of rebuilding and extensive use of spolia (Kurapkat 2015; Kinzel et al. in press). Ongoing analyses suggest that the archaeological deposits filling and covering these buildings represent settlement debris of mixed origin.

T-Shaped Pillars

The stratified limestone plateau with its vast horizontal banks varying in thickness between ~0.60 and 1.50 m was a determinant governing the locale of Göbekli Tepe: A distance of up to 700 m separates the quarry areas of the T-shaped workpieces from their final destinations. In a first step, the outlines of the monoliths were carved into the bedrock until the required depth was reached. The workpieces were then detached from the underlying strata, perhaps using wooden wedges and/or levers. The next and probably most labor-intensive step involved the transportation of the workpieces (some of which measured up to 6–7 m in length and weighed in excess of 10 t) across uneven and sloping terrain. Once at their final destinations, craftsmen would have prepared and decorated the surfaces of the pillars. Finishing touches as well as secondary iconography were likely carved once the monoliths were in the vertical. Throughout their use-lives, however, the "special buildings" including their T-pillars were constantly repaired and modified, with phases of construction, deconstruction, and reconstruction (Piesker 2014; Kurapkat 2015; Kinzel et al. in press).

Animal imagery at Göbekli Tepe is especially rich; it features at least 28 identified taxa. Notably, the pictorial composition differs between buildings, with a proportionately high number of snakes, foxes, wild boar, and vultures in Buildings A to D, respectively, and of felines in Building H (Peters and Schmidt 2004; Becker et al. 2012; Notroff et al. 2014). Where the sex of the animals is represented, they are invariably males. In addition to the diverse fauna and symbols depicted in flat relief, the buildings of Göbekli Tepe also yielded a series of anthropomorphic sculptures, usually heads, and a variety of zoomorphic figurines, reiterating the taxa shown in the flat reliefs, including, for instance, wild boars displaying their fangs or snarling predators (Schmidt 2008, 2010). Some of these sculptures have conical taps

which were used to insert them into the walls of the buildings. Figurines positioned in situ invariably evoke a feeling of danger since "charging" the observer. Sometimes animals were carved at mid-shaft height, such as the high relief of a leopard in Building C (Fig. 5).

Göbekli Tepe: Agriculture and Domestication, Fig. 3 Building D, Pillar 31. T-shaped pillar exhibiting the arms, hands, a belt, and a loincloth made of a fox skin. (© DAI, photo N. Becker)

Whereas the narrative nature evoked by the complex imagery and its "intimidating" aspect in particular has been reiterated at several occasions in literature, different opinions circulate about the function of animal symbolism at Göbekli Tepe and the ideological concept and imaginations underlying it (e.g., Peters and Schmidt 2004; Schmidt 2006; Becker et al. 2012; Benz and Bauer 2015). Clearly representing places of ritual significance to the communities involved in their construction and decoration, the very nature of past activities in the round-oval buildings is difficult to address with the material culture at hand. One possible exception are rituals involving dancing. Such performances might be indicated by depictions on the T-shaped pillars showing dancing cranes. Of interest is the fact that the lower legs of these birds exhibit an "inverse" anatomy which, together with their relative "thickness," lend a human-like appearance to the Göbekli Tepe cranes (Peters et al. 2005b). Apart from similar (but anatomically correct) depictions showing dancing cranes, the Neolithic site of Çatalhöyük also produced the articulated bones of a crane wing with specific cut marks, a find tentatively interpreted as a component of a costume used in ritual performances (Russell and McGowan 2003). That said, the main narrative of Göbekli Tepe seems to be related to the afterlife, which the PPNA community addressed

Göbekli Tepe: Agriculture and Domestication, Fig. 4 Area L9-56, Space 8. Example of a rectangular structure. (© DAI, photo L. Clare)

Göbekli Tepe: Agriculture and Domestication, Fig. 5 Building C, Pillar 27. Zoomorphic sculptures representing wild boar and carnivores and a high relief of a snarling predator, likely a leopard. (© DAI, photos K. Schmidt, D. Johannes)

within a communal memorial or other social context (Schmidt 2006; Notroff et al. 2016). However, whether the impression of fear evoked by the naturalistic depictions could have been intended to foster social cohesion and control (Benz and Bauer 2013) remains to be seen.

Subsistence

Located in the Southern Piedmont of the Southeastern Taurus overlooking the northern Harran Plain, the site possessed an ecologically highly diverse catchment area with permanent as well as seasonally available and storable bio-resources. Whereas the rectangular buildings (Schmidt 2012; Kurapkat 2015) and only recently discovered PPNA settlement areas (Clare et al. 2019) promise novel insights into foodways, storage practices, waste disposal, etc., the realization that the previously studied materials recovered from the excavated sediments of the "special buildings" in fact stem from relocated and chronologically mixed settlement debris seriously hampers deepening insights into diachronic human subsistence behaviors for this part of the site.

Notably, the supposed domestic function of the rectangular buildings (Kurapkat 2015) now appears to be confirmed by studies of significant concentrations of grinding stones (+10,000) and phytoliths illustrating extensive cereal processing at the site (Dietrich et al. 2019). Unfortunately, macrobotanical remains are poorly preserved in the contexts excavated so far; their analysis illustrates the exploitation of wild einkorn (*Triticum boeticum*), wild barley (*Hordeum spontaneum*), and possibly wild rye (*Secale cereale*) as well as non-cereals, like almonds (*Prunus*) and pistachios (*Pistacia*) (Neef 2003; Dietrich et al. 2019). Although limitations of sample size preclude conclusions about the relative contribution of each of these plant foods to the Göbekli Tepe diet, cereals appear of major nutritional importance, similar to other early Neolithic sites in the Upper Euphrates Basin and in marked contrast to contemporaneous sites in the Upper Tigris region, except for Çayönü (Cappers 2014). Use-wear analyses combined with experimental studies indicate that handstones and grinding bowls, or slabs, were the basic components of the tool kit used for processing cereals. The latter included dehusking in special grinding bowls with perforated bases and the preparation of coarse and fine flour, as can be deduced from the combined results of use-wear analyses and experimental work (Dietrich et al. 2019).

For the moment it cannot be decided whether wild cereals were also processed in the monumental round-oval buildings. Of interest, however, is

the fact that the grinding stones found there were used for grinding ochre. A prominent case are the grinding stones and ochre-rich sediments associated with the podia of the central pillars in Building D. Conversely, ample grinding equipment has been found in the rectangular buildings, predominantly in upper room fills and therefore not immediately above the floors. Arguably, relocation from the rooftop following the collapse of the ceiling could account for this observation, though for each context, the consideration of other potential explanations is essential. While the ongoing study of site formation processes will help to clarify those processes which could have led to the dislocation of grinding equipment, the overall high density of grinding stones and tools in the rectangular architecture and open spaces surrounding the monumental buildings does illustrate that there was extensive cereal processing on-site in PPNB times. As such, cereal processing on the roof of the rectangular buildings would undoubtedly have taken advantage of the wind carrying away the husks. Additionally, the processing of cereal could have had communal character, perhaps undertaken in the frame of work feasts connected to the monumental buildings (Dietrich et al. 2012, 2019). In the rectangular buildings, a spatial connection between the preparation and consumption of cereal foods is also suggested by the presence of large stone vessels that may have served several purposes including food preparation and storage of staples, thus protecting valuable foodstuffs against seed-eating rodents, birds, etc. Cereals may also have been fermented in these containers, thus producing a low alcoholic beverage (Dietrich et al. 2012).

Here we note that the archaeological record associated with the monumental round-oval buildings does not illustrate any of the aforementioned domestic activities. Therefore, given the temporally overlapping use of the round-oval and rectangular buildings, this dichotomy seems primarily functional, with a principally ritual instead of domestic use for the monumental architecture. In a way, this situation seems reminiscent of Jerf el Ahmar, where rectangular buildings with toolkits for cereal processing are arranged around communal circular buildings. However, the latter are smaller-sized compared to Göbekli Tepe and subdivided into cells (Willcox and Stordeur 2012). As these cells contained higher than average concentrations of cereals (mostly barley), the building was interpreted as a communal silo. Contrary to Jerf el Ahmar, however, the lack of relevant botanical finds in the floor sediments in the Buildings C and D at Göbekli Tepe does not support such an interpretation.

Archaeofaunal remains illustrate that meat procurement at Göbekli Tepe relied on hunting and fowling. At all times predominantly Persian gazelle (*Gazella subgutturosa*), wild cattle (*Bos primigenius*), and Asiatic wild ass (*Equus hemionus*) were hunted. Occasionally, wild boar (*Sus scrofa*), wild sheep (*Ovis orientalis*), red deer (*Cervus elaphus*), brown hare (*Lepus europaeus)*, and fox (*Vulpes vulpes, V. cana*) were added to the hunter's bag. A highly diverse avifauna complements the broad-spectrum subsistence practiced by the site inhabitants. It mainly includes ducks, geese, partridges, sandgrouse, cranes, bustards and several birds of prey, as well as more than 20 species of passerines, varying in size from bunting to raven. Occasionally, the presence of small-sized cyprinid fishes was noted, implying exploitation of the Balikh River catchment downhill. We also noted that in contrast to iconography, snake remains are extremely rare. Find context and skeletal completeness indicate that these reptiles died during hibernation. Finally, in contrast to most contemporaneous early Neolithic sites located deeper in the Southeastern Taurus, the absence of wild goat (*Capra aegagrus*) at Göbekli Tepe is noted. This we explain by the lack of suitable orographic habitat with rocky outcrops and steep slopes at higher altitude in the site catchment exploited by the site inhabitants.

Body part representation, skeletal size, sex, and age of key food mammals indicate that meat procurement was based on hunting. Transportation logistics explain why in large game, such as aurochs or red deer, bone elements of the meat-bearing body parts are statistically overrepresented at the detriment of those of the feet, the trunk, and the head. Conversely, medium-sized game like gazelle is represented by far more balanced skeletal inventories implying transportation

uphill of animals in toto. In contrast to the Göbekli Tepe iconographic repertoire in which aurochs and their bucrania figure prominently, the complete absence of skulls in the faunal assemblage studied so far (+120,000 specimens) is remarkable. Arguably, the fact that past archaeological excavations did not produce tangible evidence for this highly symbolic item could relate to the secondary nature of the contexts excavated so far. Alternatively, perhaps the bucrania carved on the pillars served as a substitute for it (Fig. 6).

Demographic profiles and stable isotope analysis of major game species suggest that hunting of gazelles and hemiones likely peaked in late summer and autumn, when these gregarious and migratory taxa visited the Göbekli Tepe catchment in numbers (Lang et al. 2013). Nemrik, Helwan, Byblos, and other projectile points indicate the use of bow and arrow and perhaps of spears for hunting, which is supported by the find of a right humerus of an aurochs cow with an embedded flint projectile point (Pöllath et al. 2018). The impact of the shot (or thrust) sufficed to pierce the soft tissues and impede the animal, which must have been dispatched shortly thereafter in view of the lack of reactive bone tissue near the impact point. The circumstances of this find imply collaborative rather than individual hunting of this formidable game, a situation tellingly illustrated at Çatalhöyük (Mellaart 1967; Russell 2012). Whereas communal hunting of aggregations of gazelle and hemione secured meat procurement and probably helped to build up supplies, aurochs were clearly more dangerous adversaries; furthermore, they were ritually charged animals which, considering their large meat and fat yields, likely prompted feasting due to surplus, thereby strengthening group cohesion. Beyond food, the aurochs' symbolic role is repeatedly attested in the archaeological record of the Neolithic Near East (e.g., Meier et al. 2017) and visualized at Göbekli Tepe by individuals carved in different poses (Peters and Schmidt 2004; Becker et al. 2012).

Human Remains

Osteological analyses of human bone from Göbekli Tepe began in 2009, and a total of 691 fragments have so far been recorded (Gresky et al. 2017). The preservation of human bone can be described as "moderate"; many pieces feature a thick cohesive layer of minerals (sinter) that is known to promote fragmentation. The bulk of human bone recovered during archaeological investigations stems from the mixed settlement debris excavated within the round-oval monumental buildings. For this reason, it is conceivable that many of these bones originate from displaced primary and secondary human burials and/or skull caches associated with disturbed domestic contexts, a conclusion that is further supported by signs of artificial modifications, including cut marks and burning.

Among the artificial modifications is a previously undocumented type of postmortem cranial modification that is thought to be a variation of early Neolithic skull cult so far distinct to Göbekli Tepe (Gresky et al. 2017). Cranial fragments from three individuals show evidence for a substantial cutting on the outer skull vault. Notably, in the absence of primary and secondary burials at Göbekli Tepe, these intentional deep incisions (which pass along the sagittal axes of the crania) have provided the very first osteological evidence

for the treatment of the dead at Göbekli Tepe. This evidence suggests that the skulls of certain individuals were removed from the post-cranium in the frame of secondary burial rites, as reported from other sites in Anatolia (cf. Hodder and Meskell 2011; Notroff et al. 2016). Although the selection criteria are unknown (and in spite of their poor preservation and high fragmentation), in two cases, the skulls could be attributed to adult individuals (25–45 years), one of whom was probably female.

The application of deep incisions to the skulls of selected individuals suggests that these people were either (positively) venerated or (negatively) "branded" by the living. Whatever the case, the grooves likely served the functional modification of the skull for display purposes, perhaps holding a cord which would have otherwise slipped from the smooth surface of the skull. This cord would have held the lower jaw in position and could also have been used to attach decorative elements to the cranium. Finally, the drilled perforation at the left parietal of one of the skulls could indicate that it was suspended for display purposes.

Early Neolithic Worldview and the Dawn of Husbandry

Animals figure prominently in the Near Eastern PPN sociocultural landscape. This is reflected by the increased evidence for long-lasting symbolism, cult practices, and representations with complex social and cosmological meaning. Feasting events and the social competition that is played out within them have, for instance, been suggested at Hallan Çemi (Rosenberg et al. 1998) in the Upper Tigris River Basin, where pig-centric feasting events were socially important, and in central Anatolia and the Levant, where bovine-centric feasting practices predominate (Buitenhuis 1997; Meier et al. 2017). In addition to feasting, the abundant and rich iconography including paintings, engravings, plastered relief figures, mounted bucrania, figurines, and sculptures indicates a prominent symbolic role for animals in early Neolithic cosmology and ritual practice. Current research therefore increasingly explores the social and religious uses of animals as motivating factors in the process of ungulate management and domestication (Peters et al. 2017).

Conceivably the most revelatory aspect of Göbekli Tepe is the tangible architectural and iconographic evidence of a complex belief system and a hierarchically structured universe at the Epipalaeolithic-Neolithic boundary. The fact that the anthropomorphic T-shaped pillars have been decorated with a variety of animal taxa, many of them dangerous to humans, e.g., aurochs, brown bear, wild boar, leopard, snakes, scorpions, etc., could perhaps signify that the supranatural beings evoked by the T-shaped pillars exerted power over these animals and thus – in the figurative sense – over the world of the living. If symbolism at Göbekli Tepe would indeed reflect "mental" control over the living world, "physical" and hence human control over animals may have been logical next steps, resulting over time in the emergence of novel ways of ungulate exploitation and management and ultimately domestication. Similar and other considerations led Cauvin (1997) to argue that the emergence of religious concepts played a catalytic role in the transition from hunting to farming.

Most researchers agree that a sedentary way of life and long-term acquaintance with the wild ancestors were required for a closer human-ungulate relationship. The latter however necessitated at some point spatial isolation of individuals from their free-ranging relatives (and thus interrupting gene flow) to consolidate the increasingly time-consuming efforts of selection and controlled breeding in the anthropogenic environment. Applying traditional archaeozoological methods to demonstrate human interference with the life cycle of an ungulate taxon during initial management when hunting activities continued providing the bulk of the meat (and hence of the osseous remains in the assemblage) is problematic, but a promising venue could be the study of intra-articular osteopathologies (Zimmermann et al. 2018). Unfortunately, the mixed origin and uncertain stratigraphic position of the fill materials in the round-oval and rectangular buildings studied until now preclude addressing the issue of possible emergence of ungulate management at Göbekli Tepe.

Building activities as well as carving, moving, decorating, and positioning T-pillars required manpower and effective logistics, e.g., in terms of food provisioning. Conceivably, the fact that several animal motifs, featuring leopards, cranes, vultures, scorpions, snakes, and aurochs, were widely shared across early Neolithic Upper Mesopotamia may well attest to the presence at Göbekli Tepe of groups of hunter-gatherers originating from different parts of the northern Fertile Crescent (Peters and Schmidt 2004; Notroff et al. 2014). If so, people from geographically distinct communities may have utilized occasional large-scale gatherings to exchange knowledge and experiences relative to the exploitation of key food taxa including gazelle, wild sheep, wild goat, wild boar, aurochs, and Asiatic wild ass. This way, more efficient hunting techniques and strategies or even novel methods for monitoring and controlling migratory wild ungulates crossing the site catchment could have spread in the community. The same is true for aspects concerning the practicability, workload, and economic benefits of penning and breeding hoofed animals inside residential areas, a practice discernible, for instance, by accumulations of dung and urine salts, e.g., at Çayönü (Brochier 1993) and Aşıklı Höyük (Özbaşaran 2012; Abell et al. 2019), and the aforementioned osteopathologies (Zimmermann et al. 2018). Not only would such dissemination scenario be consistent with the available bioarchaeological evidence indicating broadly contemporaneous appearance of husbandry practices across the (northern) Fertile Crescent, it would also highlight why the mid-late ninth millennium calBC management of ungulates was not restricted either to a single mammalian species or to taxa confined to a particular ecogeographic setting (Peters et al. 2014, 2017). In this respect, wild sheep and wild goat are seasonally migratory species inhabiting temperate to arid habitats, the first feeding on grasses in grasslands and open woodlands in hilly country at moderate altitude and the second subsisting on a mixed diet of grasses, herbs, and shrubs in landscapes characterized by steep slopes and rocky outcrops at higher altitude. Depending on water and tree cover for their survival, Southeastern Anatolian aurochs and wild boar certainly preferred the more temperate environments offered by alluvial plains, riverine habitats, gallery forests, and adjacent open woodlands, where the first essentially foraged on grass vegetation and the second on a wide variety of food items including tubers, roots, seeds, and fruits as well as the refuse resulting from human food preparation and consumption.

The fact that livestock management can be evidenced in the Upper Euphrates Basin in the later Early PPNB ~8,500–8,300 calBC (Peters et al. 2017) allows us to postulate the initial stages of these efforts to the first half of the ninth millennium calBC, if not earlier. Arguably, social obligations to participate in important communal events and the status gained through provisioning such events with animals may have been prominent motivational factors that drove the costly and failure-prone initial stages of ungulate management and husbandry. Although the precise relationships between animal symbolism, ritual practices, communal feasting, and the origins of animal husbandry are difficult to articulate, the early stages of livestock management were obviously situated within a cognitive world in which animals played a central and symbolic role. It is therefore likely that the symbolic associations of animals in the PPNA, richly expressed at Göbekli Tepe and related sites, and the ontologies that they represent provided a meaningful context which framed and stimulated the emergence of animal husbandry (Peters et al. 2017).

Toward the end of the ninth millennium calBC, Göbekli Tepe was abandoned. It is telling that this step coincided with major shifts in subsistence practices in the Upper Euphrates River Basin, more precisely the intensification of crop cultivation followed by the domestication of cereals and pulses (Tanno and Willcox 2006) and the replacement of gazelle hunting by sheep and goat husbandry (Peters et al. 2005a, 2014), signaling the end of the foraging way of life in this part of Anatolia. With the spread and intensification of agriculture increasingly tying workforce from Middle PPNB times onward, the sociocultural importance of supra-regional ritual places along with the motivation and manpower to maintain

"ancestral" monumental buildings inevitably declined in favor of local communal activities that included the construction of small-scaled cult buildings, as illustrated at Nevalı Çori (Hauptmann 2011). The rich PPNA legacy outstandingly displayed at Göbekli Tepe was nonetheless commemorated long after people had left behind their hunter-gatherer past, animal symbolism still surviving in the collective memory of Pottery Neolithic groups populating Anatolia and Syria in the eighth and seventh millennia calBC, e.g., at Çatalhöyük (Mellaart 1967) and Bouqras (Clason 1999).

Introduction

The Gobustan Rock Art Cultural Landscape, 40° 7′ 30“ N latitude and 49° 22′ 30” E longitude, is located within the Gobustan State Historical-Artistic Reserve, in the territories of two administrative districts, Garadağ included in the Baku city administrative territory, and Abşeron, 60 km south, the Azerbaijan capital city, Baku. The rock art area has more than 6,000 petroglyphs on more than 1,000 rocks with a long chronology, from the Upper Palaeolithic to historical times (Fig. 1).

The Gobustan National Park covers 4,535 hectares and includes five main rock art concentrations: Böyükdaş, Kiçikdaş, Jingirdağ, Şongardag, and Şikhgaya. The total area of the World Heritage Site is 537.22 hectares.

On September 9, 1966, the area enclosing Böyük Daş, Kiçik Daş, and Jingirdağ-Yazılitepe was declared a State Historical Artistic Reserve, referring it as a special protected historic-cultural site of world significance.

In 2007, at the XXXI Session of UNESCO, which was held in Christchurch, New Zealand, the Gobustan Rock Art Cultural Landscape Complex was included in the “World Cultural Heritage”

list. In the same year, Gobustan acquired the designated status as a National Reserve.

Definition

Gobustan, which means the "land of dry riverbed," is characterized by a rocky landscape, within a semiarid environment. The region is at the south-eastern appendix of the Great Caucasus range, on the west bank of the Caspian Sea, on the northern edge of the subdesert plane called Shirvan Steppe, and represents a landbridge between Europe and Asia.

The geology of Gobustan comprises a thick limestone sedimentary rock that has within its matrix numerous species of bivalve shells of *Didacna* sp.; a fossil record, testifying the submersion of the region during the Pleistocene era (Arslanov et al. 2015). The characteristic terraced profile of the three upland areas, Böyükdaş, Kiçikdaş, and Jingirdağ-Yazılitepe, is a clear evidence of ancient coastal lines onto which the first human groups landed and settled down. These terraces are the results of the Caspian Sea repeated regression and transgression activities (Sigari 2017), so it is possible to use the Caspian eustatic movements as a valid chronological indicator for the rock art chronology (as well as other archaeological factors). According to Arslanov et al. 2015, following the maximum stage of the Early Khvalynian transgression (+48 to +50 m asl), two more transgressions of +35 and +22 m also occurred during a period of deglaciation, approximately between 16 and 14 ka cal. BP (Arslanov et al. 2015). Finally, between 14 and 12 ka cal. BP, other two transgressions occurred, reaching altitudes asl of 0 and –12 m, probably corresponding to an Allerød warming phase the former, to the warming at the end of the Younger Dryas the latter (Arslanov et al. 2015; Sigari 2017). So it is plausible to state that the first inhabitants of the Gobustan region were also responsible for the production of the first rock art during what is referred to as the Early Khvalynian Transgression (Sigari 2017) (Fig. 2).

Early Studies and the Archaeological Context

The first Gobustan engravings were discovered in May 1939 by Ishag Jafarzade. However, due to events in World War II, the systematic researches did not start until 1947.

The first scientific study of Gobustan rock art is attributed to the prominent Azerbaijani archaeologist Ishag Mamedrza Jafarzade, who undertook fieldwork during the mid-1960s, recording more than 3,500 petroglyphs, that included anthropic hollows and holes, on more than 750 rocks (Jafarzade 1973).

Gobustan Rock Art Cultural Landscape (Azerbaijan), Fig. 2 (**a**) Panoramic view of Böyükdaş and its terraces; (**b**) Seashell fossils enclosed in the limestone rocks. (Photos by D. Sigari)

Following the work of Jafarzade, archaeologists C. Rustamov and F. Muradova continued archaeological research in Gobustan, unearthing a long chronological multilayered stratigraphy that revealed from Upper Paleolithic to Middle Age (Rustamov 1994; Rustamov and Muradova 2008). The archaeological excavations were undertaken in a number of rock shelters. Forty kurgans, a multiple burial (ten adults and one child) in Firuz, a possible sanctuary in Yazılıtepe, Bronze Age settlements, and thousands of archaeological artifacts were uncovered. Muradova and Rustamov recorded nearly 400 new engraved stones, increasing the number of rock art sites to more than 6,000 engravings on a 1,000 rocks (Rustamov and Muradova 2008). Comparing the stratigraphic sequences of each of the rock shelter sites, it was possible to correlate them and establish a more precise chronology.

According to Rustamov (2006), the first occupation phase was between 20 and 17 ka BP. Recently published datings may confirm this, even though their archaeological contexts have not yet been officially sanctioned or published (see Sigari 2017: 57). A study on eustatic rise of the Caspian Sea was proposed in (Sigari 2017). The study suggested that a variety of locates were utilized, from hilltops to the lower beaches.

Based on the archaeological evidence, a Pre-Pottery Neolithic burial unearthed in Kaniza and some artifacts, the Neolithic was underrepresented, probably due to a natural catastrophe occurred in Gobustan, which is recognized through a number of different rock displacements that occurred in the early years of the Mesolithic-Neolithic transition (Rustamov 2006).

Later during the Bronze Age, it is possible to recognize a strong influence by other Caucasian cultures, e.g., the "Kura-Arax," "Maykop," and "Khojaly-Gadabay" (Muradova 2011).

The continuous occupation of the region, dating the Upper Palaeolithic to the Middle Ages, involved the production of rock art as well (Rustamov 2006). In terms of rock art chronology, five main horizons were recognized: Horizon I (Upper Palaeolithic-Mesolithic), Horizon II (Neolithic), Horizon III (Bronze Age), Horizon IV (Iron Age-Antique), and Horizon V (Middle Age and later) (Farajova 2009).

In terms of engravings techniques, Gobustan rock art is usually scratched and/or abraded into the limestone rocks, with exception of only two red painted figures (Rustamov 2006). The main themes include the auroch, horse, boats, feminine silhouette, warrior-hunter, goat, camel, tamga, deer, and rider. Each chronological phase has its own distinct style and subject matter.

The Most Ancient Rock Art: The Upper Palaeolithic

The most ancient phases of Gobustan rock art can be attributed to the end of Pleistocene era and are concentrated in and around Böyükdaş, Kiçikdaş, and Şongardag areas.

Especially on the terraces of Kiçikdaş and Böyükdaş, the engravings can be found in open-air locates, rock shelter and caves. They are also found on erratic boulders, and on the south-eastern, eastern sides of the mountains that overlook the Caspian Sea.

The most ancient rock art can be grouped into four main categories: zoomorphs (bovid, equid, caprid), anthropomorphs (feminine silhouettes, the so-called hunters-warriors and dancers), boat-forms, and geometric signs, which are considered relatively infrequent (Fig. 3).

Zoomorphic figures were mainly portrayed adopting strategic contour line, used as a form of enhancement. In some cases, it is possible to notice how the rock features were used to represent parts of the animal body, to frame or to give a three-dimensional effect to the figures. The dominant subjects are aurochs and horses that can be coupled (e.g., Rocks No. 42-49-46b on Böyükdaş) (Fig. 4) and in hunting scenes (e.g., Rock No. 45 on Böyükdaş), or in what appear to be generic ritual scenes (e.g., Rock No. 30 on Böyükdaş).

Anthropomorphic figures are usually divided into three groups: hunters-warriors, feminine silhouettes, and dancers. Anthropomorphs usually change from the most stylized to the most naturalistic figures. These changes occur according to different chronological phases. Rustamov gave emphasis to the anthropomorphic figures which

Gobustan Rock Art Cultural Landscape (Azerbaijan), Fig. 3 The most recurrent themes in the most ancient rock art of Gobustan: (**a**) a big bovid with several anthropomorphic under and overimposed on Rock No. 29 in Böyükdaş, (**b**) Two big bovids and a horse Rock No. 49 in Böyükdaş, the eye of one of the two auroch is a crack into the rock surface; (**c**) A boat figure on the southern side of Rock No. 29 in Böyükdaş; (**d**) Feminine silhouettes, partly covered by the soil, on the northern side of Rock No. 29 in Böyükdaş. (Photos by D. Sigari)

seem to have been the first engraved. They reveal male figures to belong to a different sequence based on their size, from the smallest to the largest (Rustamov 2006). The same stylistic evolution appears in the varying shapes of boats. Sigari (2017) recently proposed a relative chronology for boat figures, whose different styles are diffused along the terraces of Böyükdaş and Kiçikdaş. These figures show some degree of uniformity, suggesting that the first boat images, which are present on the upper terraces of both Böyükdaş and Kiçikdaş, date to a period of deglaciation, which occurred between 16 and 14 ka or even earlier. A new style emerged with the adoption of the new symbols in the boat representation, such as the sun symbol one and the "X"- shaped

crew, was probably dated after 14 and 12 ka cal. BP, when the Later Khvalynian stages occurred, thus witnessing a rising sea level of between 0 and −12 masl (Sigari 2017). Zoomorphic figures, the most ancient figures of the Gobustan assemblage are usually the most naturalistic, except for, say, the smallest forms (Rustamov 2006; Sigari 2013).

The Neolithic Rock Art: Continuity with the Past Towards New Economies and Societies?

The presence of Neolithic rock art is based on the idea of the stylistic evolution of some figurative themes from the previous stage (Rustamov 2006; Farajova 2009). However, no systematic studies have been carried out yet, making hard any attempt of a substantial definition for this phase.

The Rock Art of an Ancient Complex Society: The Bronze Age

The majority of the Gobustan rock art assemblage is dated to the Bronze Age, between fourth and second millennium BCE, suggesting that the area was intensively lived in this period.

The engraved figures were portrayed adopting contour lines. They were carved on the southern and eastern sides of the boulders, occasionally they appear on the northern sides.

Engraved stones can be placed in association with other stones and/or structures suggesting a possible place of worship.

Bronze Age petroglyphs follow a stylistic tradition that is repeated elsewhere during this period, from naturalistic to schematic forms. Newly introduced figures include abstract forms, wheeled vehicles, and horseman.

The most recurrent themes of Gobustan Bronze Age rock art are: bezoar goat, cervids, and anthropomorphic imagery.

Goat images are the main subject matter and (Fig. 5) in Böyükdaş are ideal chronological markers, being not associated with the most ancient figures and, in some cases, overlapping previous carvings. This subject was found on 30 rocks out of 34 rocks, which were sealed by layers dated to the Bronze Age (Muradova 2003).

Anthropomorphic petroglyphs are mainly portrayed in two ways: the *so-called* praying figures (Fig. 6), with raised arms, and the dancers. The praying figures are extremely schematic in form, while the dancing figures have the body with a straight vertical line, open legs with wrapped knees, curved arms, a small edged head, and with clear sexual organs. Within some panel narratives, dancers are associated with goats, resembling an ethnographic folk play "Təkə oyunu," a ritual ceremonial dance occurring in this part of the world (Abdullayev 2015).

Cervid images have a proportionate body structure and are in a motion stance, sometimes turning the head backwards.

Historical Rock Art: From the Antique to Medieval Periods

At the foot of the Böyükdaş Mountain, there is inscription engraved by a centurion of the Legio XII fulminata of the Roman Army. The inscription testifies the passage of the Romans in Gobustan during Domitian's empire (AD 81–96). Medieval rock carvings can be grouped into the following categories: riders, hunting scenes, zoomorphs, geometric signs, tamgas, and epigraphic inscriptions, representing an important historical reference, confirming a long use of the site (Fig. 7).

The historical rock art was scratched and pecked using both stone and metal tools.

Zoomorphic figures appear to have different meanings. They can be considered as being reflections of everyday life, or part of a cosmogony and beliefs, e.g., goat figures which, incidentally can even assist in establishing a chronology for medieval pottery. Goat images are depicted on twelfth to thirteenth century jars (Ahmadov 1959; Leviatov 1945). These figures with curved horns are similar to those present on Gobustan medieval petroglyphs. Since goat is interpreted as a symbol of abundance and fertility, its frequent representation may be due to the semi-nomadic lifestyle of the human groups living in Gobustan during the Middle Age.

Other frequent zoomorphic subjects include cervids, camelids, predators, and horse. Humped camels can be associated with caravan scenes too. They are usually portrayed in profile-view and the chronology of these images is between thirteenth and fifteenth centuries.

An important part of the Gobustan rock art assemblage of this period is the various types of tamgas and geometric forms. According to Jafarzade's chronological sequence, the oldest tamgas date to the tenth century, even though they become a very recurrent theme between the fifteenth and eighteenth centuries (Jafarzade 1973).

Tamgas and geometric forms are found on five Gobustan mountain rock art sites, as well as

Gobustan Rock Art Cultural Landscape (Azerbaijan), Fig. 8 Rock No. 123 in Jingirdağ Mountain. Twenty 20 tribal signs-tamgas were engraved on this rock. (Photo by K.Abbasov)

on medieval grave stones and on the walls of two caravanserais: Sangachal and Miecik in Gobustan. In the latter site, these forms are underneath an inscription that dates to the fifteenth or sixteenth century. They are similar to those associated with prehistoric rock art (Fig. 8).

Tamgas were probably used for different purposes: either to mark places of residence, pointers to "natural boundaries" for tribal communities, places where important issues were settled, or on grave stones, to indicate the family lineage.

The tradition of carving stones in Gobustan continued until the nineteenth century and the local population still attribute a sacred meaning to the mountains, readapting it in the light of the Islamic tradition through the medium of art.

Key Issues/Current Debates/Future Directions/Examples

The Gobustan rock art assemblage has common problems that are also found with other open air rock art sites, such as the Côa valley, Qurta, and Siega Verde. First and foremost of these is making sense of its comprehension and meaning and chronology. Part of the solution may come from making inferences to the landscape in which the rock art is located.

Though some attempts have been made in establishing a relative chronology of rock art production (Sigari 2013, 2017; Farajova 2009) and use, further research is needed. Recent research focused on this topic (Sigari 2013, 2017; Farajova 2009; Jafarzade 1973), culminating in the "Gobustan Rock Art Recording Project," undertaken by the Gobustan National Historical Artistic Reserve commenced in 2016, will take the issue of open air rock art to the next stage beyond primary documentation. The project aims to document systematically all known Gobustan rock art, creating a digital database and a new catalogue, the result of adopting modern methodologies. The investigation is now focusing on the area of Jingirdağ-Yazılitepe (Abdullayev et al. 2016) and has already permitted to recognize 14 new engraved rocks and 521 new figures.

Advances in rock art studies and the new systematic research in the area will allow the project team to be better informed on not just the rock art per se but the ancient remnant environment in which it stands and the relationships with other rock art sites of the Euro-Caucasian region.

The analysis of represented themes, such as boats, fauna, and human figures, their distribution and relationship within Gobustan region itself and other rock art contexts, combined with the other archaeological, palaeontological, and palaeoclimatic evidence will be the key issues in further research within this fascinating key region where Asia meets Europe.

G

Goggin, John M.

Velasquez S. H. Verónica
Instituto de Ciencias Sociales y Humanidades, Área Académica de Historia y Antropología, Universidad Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, Mexico
Department of Archaeology, University of Sheffield, Sheffield, UK

Basic Biographical Information

John Mann Goggin (1916–1963) was a great mind that led a life of expedition and discovery, had vast interests and eccentric hobbies, and was a devotee of natural history. Moreover, he was an anthropologist and archaeologist committed to the history of humanity (Sturtevant 1964: 386–9).

Goggin was born in Chicago and undertook his graduate degree at Yale University. His experiences growing up in Miami with the Seminole Indians and his excursions to New Mexico and to Chihuahua with the Tarahumara, along with his passion for the great outdoors and collecting natural specimens and artifacts, influenced the way in which he understood the relationship between humankind and the natural environment. This made him increasingly aware of the problems involved in sampling and the similarities and variations within artifacts. These ideas were translated into the methodological tool known as cultural traditions, following the work of Rouse in Connecticut

Goggin, John M., Fig. 1 Majolica samples originally classified by Goggin

and that by Willey in Peru (Goggin 1964: 110). Moreover, this was applied in the St. John's region, where he identified a Spanish-Indian tradition that resulted from the impact of Hispanic culture on Indian one (Goggin 1998: 71–2).

Major Accomplishments

Goggin's main interest was the interaction between colonists and indigenous groups in the New World. His fascination for the pottery of former Spanish colonies made him aware of the necessity to create a complete typology of majolica pottery from the sixteenth to the eighteenth centuries. This drew him into studying materials from Mexico, Colombia, and the Caribbean, which culminated in the posthumous publication of *Spanish Majolica in the New World* (1968). This is a foundational study that set the basis for typological analysis of majolica in the Spanish Empire and the Indies. Along this one, *The Spanish Olive Jar* (1960) is a comprehensive typological work that emphasizes the relevance of studying these artifacts from the former Spanish colonies. Unfortunately, his untimely death in 1963 left much of his research in note and manuscript form (Goggin n.d.) (Fig. 1).

His legacy of scholarship and theoretical developments continues inspiring students and scholars alike to follow his steps in the archaeology of the former Spanish Empire and shaped the interests of scholars and students allocated in the Department of Archaeology in the University of Florida.

His work on pottery from the Indies was translated into one of the most complete databases intended for pottery identification by the Florida Museum of Natural History (http://www.flmnh.ufl.edu/histarch/gallery_types/). His emphasis on the value of combining surface collection, stratigraphic tests, typology and the use

of historical sources, and examination of works of art and artifacts in museums to study historical periods is widely used today (Rouse 1964: 372). His seminal studies of majolica, glass beads, and Spanish olive jars are still relevant reference works, although subsequent researchers have refined our understanding of these artifacts (Weisman 2002).

His personality and bequest were unique and his written works reveal his passion and profound respect for archaeological and ethnographic cultures.

Gold Museum (Museo del Oro)

Sonia Archila
Departament of Anthropology, Universidad de los Andes, Bogotá, Colombia

Basic Information

Museo del Oro ("Gold Museum")
Parque Santander, Carrera 5, Calle 16
Bogotá, Colombia
http://www.banrepcultural.org/museo-del-oro

The Bogotá Gold Museum was created in 1939 and houses archaeological objects of gold, pottery, bone, shell, stone, and textiles. The extraordinary quality of its collection of pre-Hispanic goldwork, the largest in existence, makes it unique in the world. It was established by the Central Bank of Colombia, to which the museum belongs, to save metallurgical pieces from being destroyed or removed to museums and private collections in other parts of the world, especially Europe and North America. From its foundation, the museum has valued the unique and artistic nature of the objects and their importance to Colombians as representations of a common past. The Gold Museum is by nature a national museum, the most important Museum of Anthropology and Archaeology in the country, being, from its creation, the leading institution in museology, museography, and conservation. Research programs in archaeology, archaeometallurgy, and education, the latter focusing on public primary schools, have been of particular importance.

The majority of objects forming the Gold Museum's collection have not come from systematic archaeological excavations, but rather from treasure hunters, or "guaqueros," grave robbers, and so come from the looting of pre-Hispanic indigenous tombs and places of offerings. The lack of an archaeological context for the museum's objects makes study of the social significance of the cultural material difficult, especially of the goldwork. The information that is presented to the public, therefore, comes from

various other sources, such as ethnography, ethnology, and ethnohistory, which are used to explain the objects and suggest possible meanings for them and their uses. Other aspects can be studied from the objects themselves and have been widely investigated, such as the technology and iconographic styles of diverse groups of metal objects (e.g., Plazas and Falchetti 1986; Falchetti 1995; Lleras Pérez 1999; Uribe 2005, 2007; Saenz Samper 2010).

The museum has four exhibition galleries and one interactive gallery, the Exploratorium. The first gallery is dedicated to Metal Technology. The second gallery exhibits objects produced by the different pre-Hispanic societies that existed in the territory now known as Colombia. Here, archaeological information is used to contextualize the objects of metal and other materials, emphasizing their relationship with the political and religious organization of those societies. The third gallery deals with the cosmology and symbolism of the metal objects and exhibits objects that have been interpreted as genuine examples of shamanic art by various authors (e.g., Reichel Dolmatoff 1988). The gallery of Offerings is a closed precinct, which, through exhibiting hundreds of diverse types of objects with lights and sound, evokes the Tribute Ceremony, in which many pre-Hispanic societies would use metal objects. The Exploratorium is a gallery where visitors interact across distinct Anthropological and Archaeological themes, facilitating reflection on the importance of archaeological heritage and cultural diversity.

Major Impact

History

In 1939, the Colombian government requested that the Central Bank buy pre-Hispanic gold objects in order to preserve them. Subsequently the Central Bank acquired archaeological pieces from private collections. In 1968, a building specially designed for the museum was opened (Londoño Vélez 1989). During the 1970s and 1980s, the collections were expanded and objects of pottery, shell, bone, and textile acquired. The museum considered it essential to draw on anthropology and archaeology in order to enable its exhibitions to present a more full understanding of many aspects of pre-Hispanic societies.

Towards the 1980s, the theoretical basis of archaeology in Colombia changed from being a purely traditional one that emphasized the characterization of archaeological zones, chronological sequences, and artifact classification to a processual theoretical framework that emphasized, among others, studies of settlements and relations between humans and the environment. At the museum, this change was reflected in the content of the permanent exhibition; the guidebooks used information obtained from the museum's own archaeological research (e.g., Plazas and Falchetti 1986), and from other institutions, and at the same time adopted an approach that utilized the insights of anthropology to incorporate ethnographic information and suggest uses and functions for the objects (e.g., Pineda Camacho 1986; Reichel Dolmatoff 1988).

Today

The museum was completely renovated in 2008. The museum's new exhibition constitutes a modern museographic design and includes an interactive gallery (see above) and audio visual aids specially designed for different audiences. The current museum guides separate the technological information about metallurgy, derived from the more than 30 years of investigation by the museum, from that of a more archaeological nature, which draws on current information from other researchers. Three of the new museum galleries are dedicated to the interpretation of meanings and symbols of the metal objects. Making use of ethnographic analogy, and working from the fact that various indigenous societies currently living in Colombia have ancestral links with the pre-Hispanic period, anthropological information about the cosmology, symbolism, and religious beliefs of indigenous American societies, particularly from Colombia, is used to interpret and suggest the meanings of archaeological objects.

The importance that the museum has given the country's indigenous societies contributes to valuing and respecting the present-day indigenous

peoples as part of a multicultural nation. The museum constitutes a unique space that attracts a large and diverse audience and is moreover a highly regarded institution. The Gold Museum's excellent and invaluable work of informing and educating has made it a distinguished institution in Colombia and an obligatory reference for any statements about Colombian identity.

G

Goldberg, Paul

Richard I. Macphail
Institute of Archaeology, University College London, London, UK

Paul Goldberg is a geologist by training and obtained his B.A. in Geology from the University of Colorado (1965), Boulder. For his postgraduate studies, he moved to the University of Michigan, Ann Arbor, where he studied under William R. Farrand, one of the pioneers of Geoarchaeology; he earned M.S. (1968) and Ph.D. (1973) in Geology. His doctoral dissertation was a sedimentological study of the Palaeolithic cave deposits from Tabun, Mt. Carmel, Israel.

In 1973, he moved to the Institute of Archaeology, Hebrew University of Jerusalem, Israel, to undertake a Lady Davis Fellowship. He remained there until 1991, reaching the level of Associate Professor. During this time he continued his research on prehistoric cave sediments, such as at Kebara Cave (Goldberg et al. 2007), but also began to investigate the relationship between Quaternary landscapes and environments associated with archaeological sites in the Negev and Sinai Deserts (Goldberg 1984). Concomitantly, he began to develop the

technique of micromorphology and its application to geoarchaeological problems (Courty et al. 1989; Goldberg 1980).

From 1991 to 1995, he became a Research Scientist at the Texas Archeological Research Laboratory (TARL), The University of Texas at Austin, where he carried out geoarchaeological research, examining the micromorphology of burnt rock middens and the geoarchaeology of the Paleoindian-Prehistoric site of Wilson-Leonard. In 1995, he moved to the Department of Archaeology, Boston University, as Associate and then Full Professor and was involved in teaching courses in geoarchaeology, micromorphology, and site formation processes, emphasizing the importance of documenting artifacts and their microstratigraphic context (Goldberg and Berna 2010). Around 2000 he and colleagues from Israel, China, and the USA employed micromorphology and Fourier transform infrared spectrometry (FTIR) to demonstrate the lack of ashes and fireplaces at the *Homo erectus* site of Zhoukoudian in China (Goldberg et al. 2001).

His research continues to focus on the application and development of micromorphological techniques to understand site formation, and in the last several years, he has investigated the microstratigraphy deposits from Pleistocene caves in France (Goldberg et al. 2012), Israel, Germany, Siberia, Indonesia, and South Africa. Some of these sites are related to issues of Neanderthal pyrotechnology and Neanderthal burials. He is also currently involved in the study of Iron Age/Muslim Period sites in Menorca. In 2014–2019 he was a Professorial Research Fellow at the Centre for Archaeological Science (CAS) at the University of Wollongong and remains as a Visiting Research Professor. He is also a Senior Visiting Professor at the Institute for Archaeological Science, University of Tübingen. In addition to publications in journals, he has co-authored several books that illustrate geoarchaeological and micromorphological techniques, approaches, and theory. These include *Practical and Theoretical Geoarchaeology* (Goldberg and Macphail 2006), *Applied Soils and Micromorphology in Archaeology* (Macphail and Goldberg 2018a, b) 2018, *The Middle Paleolithic Site of Pech de l'Azé IV* (Dibble et al. 2017), and *Reconstructing Archaeological Sites* (Karkanas and Goldberg 2018).

He has received a number of rewards for his work in geoarchaeology and micromorphology, including the Rip Rapp Award (Archaeological Geology Division, Geological Society of America 2002), the Roald Fryxell Award (Society for American Archaeology 2008), the Pomerantz Award (Archaeological Institute of America 2010), and several research awards from the Alexander von Humboldt Foundation (2004, 2013, 2019).

Golmsten, Vera V.

Dmitry A. Stashenkov
Samara Regional Historical Museum, Samara, Russia

Basic Biographical Information

Vera Vladimirovna Golmsten (1880–1942) was an archaeologist and a doctor of historical sciences. She was born in St. Petersburg into the family of a military doctor, Vladimir V. Golmsten. She graduated from the Gymnasium for Females at the Ministry of Public Education at the Intercession Community of Nurses in St. Petersburg in 1898 and took an additional eighth pedagogical class in 1899. In 1910 she graduated from the Moscow Institute of Archaeology. She was a student of famous Russian archaeologist V.A. Gorodtsov.

After graduating from the Institute in 1910, Golmsten spent a few months living in Ufa province. In 1911 she carried out excavations of the "Chortovo (Devil)" fortified site near Ufa. After defending her dissertation in 1909–1912, she conducted archaeological excavations in Slavic and prehistoric sites in the Pskov region and the Urals. Her life was connected with the Historical Museum in Moscow from 1911 to 1919. In 1912 she became a corresponding member of the Imperial Moscow Archaeological Society.

From 1919 to 1929, Golmsten worked in Samara as a professor of Samara University. She was a teacher of higher ethnological and archaeological courses and scientific secretary of the Society of Archaeology, History, Ethnography, and Natural History. From 1922 to 1929, she was the director of the regional museum (Kuzminykh et al. 2007).

Since 1929, after her departure to Leningrad, Golmsten worked at the State Hermitage and the State Academy of the History of Material Culture (IHMC). In 1935 she received a doctorate in history. At the end of 1930, her field studies were conducted on the Lower Don.

Vera Golmsten died of hunger on March 8, 1942, during the Leningrad Blockade in the Second World War.

Major Accomplishments

Under Golmsten's leadership, continuous archaeological surveys were conducted in Samara province on 1200 archaeological sites. Excavations were conducted on monuments of all eras, including the Paleolithic in Postnikov ravine, Bronze Age burial mounds near the stations of Bezymyanka and Red Kryazhok, an early Iron Age burial ground in Berezovka, and the fortified site era Volga Bulgaria in s. Valy – "Muromsky town." (Golmsten 1925) There are more than 100 collections by Golmsten in the Samara Regional Museum named after Alabin.

Golson, Jack

Gary T. Jackson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Jack Golson was born in 1926 and raised in Rochdale in northern England (Fig. 1). As a child of the Great Depression, growing up during World War II, he was attracted to join the Young Communist

Golson, Jack, Fig. 1 Jack and Clare Golson receiving the World Archaeological Congress' Lifetime Achievement Award at the annual meeting of the Australian Archaeological Association, Adelaide, 2009

League in his late high school years and to join the student branch of the Communist Party at university. In 1943 he won a scholarship to study history at Cambridge University but was called up for national service at the end of his first year, 1943–1944. For his national service, he was conscripted to work in the coal mines as one of the "Bevin Boys" named after the Minister of Labour, Ernest Bevin (Stewart 1998). These experiences helped to form Jack Golson's strong sense of social justice.

He resumed his history studies at Cambridge in October 1948 and almost immediately discovered archaeology in the lectures on European medieval history, which brought the contribution of archaeology to an understanding of the non-literate invaders who had overthrown the Roman Empire and laid the foundations of the European Middle Ages. Golson switched his major from history to archaeology, becoming a student of Grahame Clark. He graduated with B.A. (Hons) in 1950 (M.A. in 1952) and began doctoral research in 1951, under the joint supervision of the archaeologist Clark and the historian Maurice Postan, combining history and archaeology in the study of medieval settlement in an English county.

The doctorate was never finished because in 1953 he was persuaded to apply for a Lectureship in Prehistory in the recently established Department of Anthropology at the then Auckland University College, New Zealand. The argument was that a few years' experience of this type would justify his appointment back in England in the minority field of medieval archaeology. In fact, he had decided before the end of 1954, the first year of his appointment, that he would prefer to stay where he was.

Nevertheless, in 1961, he left the University of Auckland to take up the first position in archaeology at the Australian National University, a Fellowship in Prehistory in the Department of Anthropology and Sociology in the Research School of Pacific Studies, being certain that the ANU offered greater opportunity for a professional career in the archaeology of the region. Indeed, by 1969, the archaeological component of the Department of Anthropology was strong enough to form an independent department, with Golson as the foundation Professor of Prehistory. He retired in 1991 and continues as Emeritus Professor at the Australian National University. The Jack Golson Lecture is held biennially at the Australian National University to honor his work as a founding figure in developing modern archaeology in several nations and as an important researcher in the evolution of horticultural economies in the Pacific.

Major Accomplishments

Jack Golson is an individual of remarkable talents. His research, teaching, and professional service have had a profound impact on archaeology globally. In his early career based in New Zealand, he led in some of the first productive collaborations between Indigenous peoples and archaeologists.

In New Zealand, he saw his role as introducing the archaeological practice of stratigraphic excavation and scientific collaboration that he had learned in his student years. In 1954 he was instrumental in the establishment of the New Zealand

Archaeological Association, which became the vehicle for these aims and for his own education in a proper relationship of his discipline with the Indigenous Polynesian population, whose history he, as an archaeologist in New Zealand, was addressing (Golson 2004).

In 1957 he was invited to undertake archaeological research in Tonga and Western Samoa for the Tri-Institutional Pacific Program – the Bishop Museum (in Honolulu), the University of Hawaii, and Yale University – which was part of the post-WWII story of the growth of serious archaeological involvement in the South Pacific field. This entailed his own entry not only into the Pacific field but also into the wider one of island and mainland Southeast Asia and the Pacific, which was looked after by the recently (1953) established Far Eastern Prehistory Association (FEPA), whose American branch had launched the first issue of the journal *Asian Perspectives* on its behalf in 1957. In 1971 FEPA held one of its 4-yearly congresses in Canberra, in what is seen as a landmark meeting, in the course of which it was decided to change its colonial era name to one more appropriate to current political reality – the Indo-Pacific Prehistory Association (IPPA) (Golson 1998), in which Australian archaeologists have and continue to play an important role. These developments came at a time when the archaeological profession that had expanded so rapidly in the 1960s worked together to form the Australian Archaeological Association. In this it was helped by the fact that, from its establishment by the Commonwealth government in the early 1960s, the Australian Institute of Aboriginal Studies gave archaeology recognition as a separate discipline.

The brief that Golson had been given for the post to which he had been appointed in 1961 was to develop a program for archaeological research in Australia and the nearer islands of the southwest Pacific, with particular reference to the then dependent territory of Papua and New Guinea. Golson was joined in this task by John Mulvaney, who was recruited in 1965 to take over the direction of Australian research, leaving the Pacific, including New Guinea, to Golson. Meanwhile, to help their planning, they organized seminars to which they recruited the talent of ANU and CSIRO staff active in field research in tropical Australia and Papua New Guinea on climates, landscapes and land systems, soils, geology, botany, ethnobotany, and wildlife. Out of these came, not only, an edited book on *Aboriginal Man and Environment in Australia* (Mulvaney and Golson 1971), which now ranks as a landmark publication, but also information to help planning archaeological survey in little known Papua New Guinea.

His work of site survey and excavation for the Tri-Institutional Pacific Program was done in 1957 on the Tongan island of Tongatapu and the Western Samoan one of Upolu. From the mid-1960s Golson was a pioneer and major player in the development of archaeological studies of Papua New Guinea (Denham and Ballard 2003). In March 1992 his contribution to academic research in the region was recognized when the University of Papua New Guinea awarded him an honorary doctorate.

In 1966, at an early stage of his work in PNG, Golson discovered the potential of the Wahgi Valley swamps of the central highlands to reveal agricultural history through collaboration of archaeologists with geomorphologists and palaeoecologists. Investigations of the 1970s at Kuk Swamp, followed up by Tim Denham in the 1990s, produced evidence for the antiquity (at least 7,000 years ago) and independence of the origins in the region of an agriculture based on yams, taros, and bananas that was characteristic of the South Pacific as a whole in later times. In 2008 Kuk was given World Heritage status by UNESCO.

This was the sort of contribution to national identity that Golson and colleagues inside and outside PNG were confident that archaeology could make to a country that was moving towards independence (Golson 1970) and achieved it in 1975.

Jack Golson was one of a small group of scholars who initiated study of the interrelationships between environment, ecology, and people in the Australasian region. Seminal publications in this area include *Sunda and Sahul*: *Prehistoric Studies in Southeast Asia*, *Melanesia and*

Australia (Allen et al. 1977) and *Aboriginal Man and Environment in Australia* (Mulvaney and Golson 1971). Today, the study of people and their environments is a thriving area of research in Australian and Pacific archaeology.

Along with John Mulvaney, Rhys Jones, Betty Meehan, and others, Golson played a key role in the professionalization of archaeology as a discipline in Australia, a process that started in the 1960s and included establishment of the Australian Archaeological Association. Golson was a prime mover in many other initiatives that were critical to the development of archaeology in Australia, including establishment of a radiocarbon-dating facility at the Australian National University in 1965.

Jack Golson was President of the World Archaeological Congress (WAC) from 1990 to 1994. He and his wife Clare were present at the 1986 conference in Southampton out of which it grew. He was elected to the Steering Committee that drafted the original WAC statutes and codes of ethics for approval at the second WAC conference in Venezuela in 1990. In 2009, Jack and Clare Golson's personal and professional contributions to the World Archaeological Congress were recognized in them being awarded its Inaugural Lifetime Achievement Award.

Jack Golson's contributions to Pacific archaeology were honored by his departmental colleagues following his retirement in 1991 in the edited volume *A Community of Culture*: *the People and Prehistory of the Pacific*, published in 1993.

Gomes, Mário Varela

Tânia Manuel Casimiro
Departamento de História Faculdade de Ciências Sociais e Humanas, Instituto de Arqueologia e Paleociências da Universidade Nova de Lisboa, Lisbon, Portugal

Basic Biographical Information

Mário Varela Gomes is a Portuguese archaeologist who was born in Lisbon in 1949. He developed an interest in archaeology while still a young boy searching for the evidence of "past

Gomes, Mário Varela, Fig. 1 Mario V. Gomes in 2012

civilizations" wherever he travelled, not only in Lisbon where he grew up but also in Ericeira where his family had a summer house where he passed many months each year. The adventurous interests of his youth developed into a professional occupation. He graduated in architecture from the Lisbon Fine Arts University and studied history and archaeology at the Faculdade de Letras in Lisbon and also at other institutions in Spain, Italy, England, and Sweden. He has a Ph.D. in archaeology based on his research into pre- and protohistoric rock art sites in Vale do Tejo, Portugal (Fig. 1).

Mário Varela Gomes was the director of the Silves' Archaeology Museum and of the Montemor-o-Novo's Museum. From 1992 to 1995 he was a teacher at the Masters in Urban Centres Architectural Rehabilitation in the Fine Arts University. In 1994–97 he was one of the responsible people for the first studies from Foz Côa leading to the site's classification as world heritage, a scientific advisor for the Chauvet cave (France), and an expert in the European Commission for the 2000 Cultural Program. Today, he is a professor in Prehistory and Cognitive Archaeology with the Faculty of Humanities and Social Sciences at the New University of Lisbon.

Major Accomplishments

Mário Varela Gomes' archaeological activities have been extensive. He is responsible for the study, classification, and publication of two major rock art groups in Portugal, Foz Côa, and Vale do Tejo, as well as major discoveries in other archaeological periods. He has undertaken tracings and studied rock art engravings in many regions, including Stonehenge, Züschen, Vale do Tejo, the Arronches shelters, Escoural cave, Vale do Côa and Monte de Góios in northern Portugal. In addition, he has studied other rock and megalithic art, southwest Portuguese Bronze Age stelae, and Iron Age epigraphic stelae.

Gomes has supervised dozens of archaeological excavations in sites from all prehistoric and historic periods, including the Xarez, Portela de Mogos, and Almendres stone circles; Perdigões, Algarve, Padrão, Amantes, and Caramujeira menhirs; the megalithic graves from Pedra Escorregadia, Bulhoa, and Anta Grande da Comenda da Igreja; the Bronze Age necropolis from Vilamoura, Alfarrobeira, and Vale da Telha; and also the protohistoric settlements of Escoural and Pontes de Marchil, the Rocha Branca Phoenician-Punic factory, and the Iron Age Garvão sanctuary. Islamic archaeology is another of his major research activities, undertaken through excavations in the Silves cistern-well, castle, and urban areas and also the rural castle (husun) from Castelo Belinho where a stupendous Neolithic village was found, and in the Arrifana *Ribat*. All of his students at the New University of Lisbon remember Gomes as an enthusiastic and accessible teacher who took them on field assignments or worked with them in the lab, teaching and publishing together.

Gomes has published more than 250 books and papers dedicated to archaeology, art history, ethnology, and architecture, in Portugal and in other countries. With A. Coelho F. da Silva, he is the coauthor of the students' handbook *Portuguese Protohistory* (1998) and the founder of the scientific journal *Xelb*, published by Silves.

In his 40-year career Gomes was a presence in the major archaeology and history associations of Portugal. As vice-president of the Portuguese Archaeologist Association, the oldest archaeological

institution in Portugal, founded in 1853, Gomes was responsible for many of the association's activities over the last decade and for quite some time he was the youngest member of the Portuguese History Academy.

Despite his lifelong dedication to archaeology, Gomes is also known as an architect responsible for the concept and construction of many Portuguese museums such as the Silves, Salir, Albufeira, and Loulé. In 2003 he received the Portuguese History Academy award for archaeology and the Portuguese Archaeologist Association's silver medal. Although a recognized expert outside Portugal with published works in Spain, France, Italy, and the United Kingdom, Gomes still finds time to be a major enthusiast and advocate of local history, supporting and writing to local journals and newsletters in the defense of archaeological heritage.

Gönnersdorf (Magdalenian): Geography and Culture

Martin Street
Monrepos Archaeological Research Centre, Museum for the Evolution of Hominin Behaviour
Schloss Monrepos, Neuwied, Germany

Introduction

Gönnersdorf is one of two major Magdalenian settlements in the Central Rhineland of Germany (the other being Andernach-Martinsberg). The

site was largely saved from destruction by burial under ash deposits of the late-glacial Laacher See volcanic eruption. Analysis of a broad range of well-preserved finds and features provides detailed insights into many aspects of Magdalenian life, such as technology and subsistence economy, use of the on-site living space, medium- and long-range mobility patterns, the use of personal ornament, and forms of artistic expression.

Definition

The Magdalenian locality Gönnersdorf (Central Rhineland, Germany) is characterized by the preservation of complex settlement features exceptional for an open-air site of this age. Due to burial beneath volcanic deposits, the site offers a rare opportunity to investigate a broad range of settlement information preserved largely in situ over an area of several hundred square meters and, by comparison with other sites, integrate this within a synthetic model for Magdalenian settlement processes and land use.

Key Issues

Location and Research History

The Gönnersdorf Magdalenian site was discovered in 1968 at the western end of a step formed by the Rhine Middle Terrace, on higher land secure from flooding by the river which flows at the foot of the terrace to the north. Just west of the site the Rhine reenters the narrow channel of the narrow Rhine Gorge, leaving the open Neuwied Basin. The site is sheltered to the west and the north by higher land, and the long known Paleolithic site Andernach-Martinsberg lies in view only 2 km distant south of the Rhine.

Between 1968 and 1976, Gerhard Bosinski excavated a total of 687 m^2 at Gönnersdorf, uncovering five distinct find concentrations (Konzentration = K) K I–K IV and SW characterized by differing combinations of placements of large stone slabs, groups of pits, various lithic and faunal materials, and areas stained by ocher (Bosinski 1979).

Chronology and Environment

The chronological position of Gönnersdorf is now quite well understood (Stevens et al. 2009), with the main Magdalenian occupation falling toward the end of the cold and arid Greenland Stadial 2a (~13,800 BCE in calibrated years, with radiocarbon dates between 13,270 BP and 12,990 BP). This contradicts the initial interpretation of the site (Brunnacker 1978) as dating to the end of an interstadial (*Bølling*) phase but is consistent with the wider range of environmental/ecological information available today.

The species of the Gönnersdorf hunted mammal fauna are those typical of the open, continental to arctic *mammoth steppe*, and for Magdalenian subsistence activities (Poplin 1976; Brunnacker 1978). Small rodent remains associated with the archaeological horizons include numerous lemmings (*Dicrostonyx*) and voles (*Microtus gregalis*) typical of arctic/continental conditions. By contrast, four absolute dates for remains of woolly rhino and mammoth are older than those for the hunted ungulates by ~600/1,600 radiocarbon years and potentially represent collected subfossil material. Both species were however still part of the fauna and known to the Magdalenian hunters as demonstrated by their engraved depictions. The few specimens of post-cranial bone of two species more characteristic of wooded conditions, red deer and elk, showed a spatially limited distribution in area SW, away from the main site structures (Buschkämper 1993; Street and Turner 2012) and are certainly (in the case of a directly dated elk bone) or probably several hundred years younger than the main faunal assemblage.

Settlement Features

The artificially dug pits in the Gönnersdorf structures K I–K III have been variously interpreted as posthole settings, hearths, or cooking pits, and these three structures, also characterized by central zones of dense paving, are interpreted as stable and quasi permanent dwellings used for long-term residence (Jöris et al. 2012).

The largest, centrally located concentration (K II) can be subdivided into two subunits, a larger central area (K IIa) and a smaller area (K IIb) to the immediate northwest, each located

G

around a distinct group of pits (Sensburg 2007). K IIb has now been interpreted as an open-air activity area possibly involving the use of cooking pits (Sensburg and Moseler 2008).

K IV (at the northern edge of the excavated area) and SW (adjacent to and west of K I) have no pits and were interpreted as the remains of possibly transportable dwelling structures used only for shorter stays (Buschkämper 1993; Terberger 1997). GIS-supported analyses of lithic find densities and systematic refitting studies provide details of the inner organization of K IV and its relationship to several external areas which probably had several different functions (Sensburg and Moseler 2008).

Taken together, the investment of time and effort represented by the great quantity and diversity of accumulated material suggests that at least some of the Gönnersdorf structures were in use over an extended period of time. Many of the rocks used as constructional material show complex patterns of modification, such as splitting and notching of the edges of blocks and slabs, and this possibly represents ad hoc modification of these elements to accommodate now perished objects such as wooden stakes or supports, perhaps during multiple episodes involving reuse of the same elements. The features and material as they were uncovered represent only the final, abandoned stage of a complex development, which probably took place during repeated occupations, conceivably extending over several years.

Gönnersdorf provides no evidence for a superstratification of living floors which might enable the recognition of distinct occupation horizons, but other methods have been used to try and establish some degree of temporal differentiation. Long-distance refits of slate slabs and quartzite blocks between K IV and other concentrations produced a complex model of the relationships between these structures (Terberger 1997). In K III certain lithic raw materials occur in some pits, whereas others are never found in pits, suggesting that the dwelling was occupied on at least two and perhaps three occasions during which the several pits were variously open or already closed by infilling.

In view of this complexity, Gönnersdorf has been interpreted as the remains of a group of dwelling structures occupied intermittently over an extended period of time; several of them possibly occupied contemporaneously, in effect forming a *temporary village*. Differential spatial patterning of lithic raw materials (Franken and Veil 1983) brought the suggestion that this *village* was occupied by distinct groups of Magdalenian people with various geographical origins who possibly visited Gönnersdorf with perhaps only partly overlapping phases of occupation, conforming to a model of an aggregation camp.

Gönnersdorf provided some evidence for the use of fire. Burnt lithic artifacts are present in very small numbers and almost no bones show traces of burning. Small quantities of charcoal were identified and plotted during excavation.

Well-defined evident structures recognizable as hearths are rare. The clearest evidence comes from K IV, where complexes of fire-cracked and reddened quartz and other rocks at the center of the dwelling structure and outside this are interlinked by refitting. The presence of an internal hearth at the center of the large K I structure is suggested by a pit containing charcoal and burnt quartz. The use of fire at Gönnersdorf is also shown by quantities of thermally reddened slate and quartzite slabs and cobbles and fire-cracked quartz pebbles interpreted as cooking stones (Brunnacker 1978). Their location provides an indication of areas in which fires may have burned, but the absence of clear hearth structures suggests that thermally altered rocks were moved after contact with fire, perhaps being used repeatedly in different parts of the occupation area. Such multiple use of hearth construction materials during different occupations or phases of activity would remove or blur traces of earlier activities.

The non-cryptocrystalline rocks brought to the site did not only serve as constructional material, and many of them were transformed into various forms of artifacts. Fragments of geodes and conglomerate with naturally concave surfaces and slate slabs with artificially hollowed depressions are believed to have served as lamps fueled with animal fat, and it can be discussed whether light and heat within the dwellings were provided by

these and not by open fires (see above). Some of these objects probably served as mortars for grinding red hematite, a material found at the site, sometimes in the form of clearly abraded or facetted pieces.

Different types of pebbles obtained from river gravels were used as hammer stones for stone working or for the secondary retouch of lithic artifacts in manufacturing tools. Larger cobbles probably served for processing other inorganic or organic materials, by crushing, pounding, or grinding. More than 400 small perforated slate disks and their fragments were found. Many of them are engraved with geometric patterns, although it is sometimes clear that disks were manufactured from fragments of slate that had been engraved previously. These finds are not necessarily or principally symbolic items but may have had a practical function, perhaps as aids in fastening together hides which are presumed to have covered the dwelling structures.

Lithic Artifacts and Group Mobility

The Gönnersdorf site produced a total of almost 82,000 lithic artifacts (Floss 1994). The majority comprises exogenous flint (>50,000 artifacts) with regional to local materials (forms of limnic quartzite (~15,000) and lydite (~12,000) making up the balance). Smaller groups of material include chalcedony (~3,000) and indurated oolite (~2,000), while a small number of artifacts are made of probably exotic semiprecious stones such as rock crystal, opal, or jasper.

The flint was derived from various sources. Good quality Cretaceous flint (*Western European Flint*) was obtained from primary chalk formations in the region of the Belgium-Dutch-German border, some 120–130 km to the northwest and in derived form from river terraces in the western part of the Lower Rhineland. This material characterizes K II in particular and is associated with a small quantity of probably Mesozoic quartzite, probably imported from the same region. A second variety of Cretaceous flint (*Baltic Flint*) was obtained from moraines left by the antepenultimate glaciation, the nearest of which are immediately north of the River Ruhr, some 100 km north of the Central Rhineland.

The chalcedony and indurated oolite (*Kieseloolith*), which are quite important in structures at the north of the Gönnersdorf site (K III, K IV), were very probably obtained from the Mainz Basin and lower Main valley some 80–100 km to the southeast.

The exogenous lithic raw materials are generally accepted as proxies for the mobility of Paleolithic groups or individuals, and the sources of the flint suggest possible contacts from the Central Rhineland to the Magdalenian of the Rhine-Meuse loess region (and possibly further west to the Netherlands or Belgium) on the one hand and to the eastern Lower Rhineland and perhaps further to the north and east on the other. The materials obtained from southern sources could indicate contact to southern German Magdalenian groups.

Fine-grained Tertiary limnic quartzite occurs in the region at numerous localities (outcrops, block fields) and was probably available within a range of some 30 km, perhaps being targeted by middle-range expeditions during the occupations of the Gönnersdorf site or collected during the initial journeys to the sites.

Intensive use of the local raw material lydite, obtainable in the Rhine gravels, might reflect a late phase of site occupation prior to leaving the region, when expeditions to obtain raw material were not an option. Alternatively, it might simply represent ad hoc collecting of a poor quality rock type during periods of low mobility. This material is predominantly found in structure K I.

The varied origin of the Gönnersdorf lithic raw materials has contributed to an interpretation of the site as a meeting point of distinct Magdalenian groups from different regions. It is possible that these groups met at Gönnersdorf, which would then have the character of an *aggregation camp* or *base camp*. Alternatively, a single larger group occupying the Central Rhineland may have dispersed into different regions at certain times of the year and brought back specific materials from these regions.

Subsistence

At Gönnersdorf the most important food species in all investigated structural concentrations is the

horse. In the largest assemblage, from K II, some 2,100 postcranial specimens and 850 cranial and tooth fragments must come from at least 28 animals. K I produced more than 1,500 horse remains, representing at least 12 individuals, while at least 7 individuals of horse are represented in K III by c. 300 specimens. At least five horses are represented by 150 specimens in the SW structure, whereas at the north of the site, 159 identified specimens in spatial association with the K IV structure demonstrate only two horses. The total number of horses represented at the site is thus 54, if the figures established for the different concentrations are added together.

Other large and small mammal species, together with some birds (raven, ptarmigan, swan, goose, snowy owl, and seagull) and very few fish remains (trout, burbot, and a cyprinid), play a far less significant role in the diet; indeed not all of the identified species represent a food resource. Specimens of a rhinoceros maxilla and mammoth bone and ivory are shown by radiocarbon dating to be subfossil remains collected possibly as a curio or for use as raw material (ivory) or a constructional element (mammoth femur). Much of the material identified as reindeer is in the form of antler tools or their waste, in some cases demonstrably collected shed antlers. Teeth and foot bones of wolf might represent pelts rather than animals hunted locally while bird remains, in particular wing and foot bones, may derive from ornamental feathers and claws. A large bovine, chamois, and saïga antelope are represented by at most one or two animals and cannot always definitively be demonstrated to represent animals hunted for food.

Many other faunal remains clearly do represent the animals hunted during human residence at Gönnersdorf. A number of cut-marked and fractured bones reveal standardized stages of butchering. Skinning, disarticulation, and filleting of meat can be identified, along with intensive bone fracturing for obtaining marrow and grease.

The composition of the faunal assemblages of the various structures shows clear differences. Arctic fox is the most common species in K I (c. 2,500 specimens from at least 30 animals), probably as a result of winter trapping for furs, followed by horse and varying hare. By contrast horse dominates the assemblage of K II and less than 200 remains of arctic fox were present. Hare overtakes arctic fox in importance with more than 400 specimens. Several other species present here (large bovine, rhinoceros, chamois) are not represented in K I. It was noted above that their role in the diet is sometimes unclear. Some 280 bones and teeth of reindeer from K I represent at least three hunted animals, whereas of the c. 170 pieces of antler, some were demonstrably brought to the site as shed specimens. Reindeer is represented in K II by some 350 specimens of bone, tooth, and antler, but no more than one individual can be demonstrated here.

The presence in K III of bones of the large bovine, rhinoceros tooth fragments, and chamois teeth suggest that it was somehow linked to the adjacent K II. Apart from horse, described above, K III also produced 71 finds identified as arctic fox (no more than one individual), c. 100 specimens of varying hare, and over 200 specimens of reindeer from at least two animals.

Faunal remains are comparatively poorly represented in the northern area of K IV and at the southwestern part of the site (SW). The smaller species fox and hare are absent or exceedingly rare, and reindeer is absent from K IV and represented by less than 20 finds in the SW area, where it might be argued that some or all of this is waste discarded from adjacent K I and K II.

Organic Artifacts and Objects of Adornment

The numerous artifacts of bone, antler, and ivory found at Gönnersdorf are typical for the later Magdalenian. They include eyed needles of bone and the cores from which they were manufactured, mainly horse metapodial bones. Spalls and projectile points, batons percés, and baguettes demi-rondes were made of reindeer antler, and waste debitage shows the manufacture of such items at the site. K I, K II, and K III produced a small number of mammoth ivory artifacts, such as projectile points or a perforated disk, and debitage mainly in the form of small fragments.

Various types of material modified to objects of personal adornment were found. Red deer is

mainly represented at the site by teeth or tooth fragments modified as personal adornments, among them a group of six perforated canine teeth in K I and fragments of incisor teeth modified by removal of the roots in K II. These probably have nothing to do with subsistence and may have been imported over a large distance. This is certainly the case for perforated marine mollusk shells (*Homalopoma sanguineum, Dentalium*), which are ultimately derived from southwestern Europe and provide evidence of contact between the Mediterranean or the southern French Atlantic coast and the Central Rhineland. Whether their transport over a distance of some 800–1,000 km reflects the mobility of individual persons or human groups is unknown.

Reindeer incisors were cut or sawn as articulated series from the mandible, and the presence of the removed roots shows that in some cases, these were certainly manufactured at the site. This also applies to the canine, incisor, and premolar teeth of arctic fox which were removed from the jaws and perforated for suspension. Some specimens of collected fossilized wood are equivalent to jet in their density and appearance and were used for the production of beads. That this took place on site is demonstrated by half-finished specimens. A small pit in K I contained several jet beads associated with perforated teeth.

Art

Among the most interesting finds from Gönnersdorf are numerous slabs of slate engraved with figurative art, including depictions of women (Bosinski and Fischer 1974; Bosinski et al. 2001) and many species of animals (Bosinski and Fischer 1980; Bosinski 2008), together with abstract symbols.

The highly schematic human female depictions are shown with pronounced buttocks and sometimes with breasts, but without head and feet, and are often arranged as pairs or in groups to form scenes interpreted as dancing. The abstract style is typical of the period and is also known from neighboring regions. Female figurines in the same style are normally carved of ivory, but specimens made of antler or stone are also present at Gönnersdorf.

The most commonly depicted animal species represented are horse and mammoth (Bosinski and Fischer 1974), with representations of woolly rhinoceros, large bovines (bison and aurochs), red deer, reindeer, saïga-antelope, wolf, bear, lion, and seal present in far lower numbers. There are few engravings of birds and rare examples of fish, reptiles, and amphibians. The realistic engravings clearly prove that these species were well known to the artists, but they may have encountered or observed some of them in other regions and not in the Central Rhineland. Very rarely the engraved figures appear to be grouped together to form a narrative or symbolic scene.

The Gönnersdorf art mirrors the wealth of artistic expression from Magdalenian caves in Western Europe and suggests the complex social activities which occurred at the site.

Season and Duration of Occupation

Seasonality information from the analysis of the faunal remains suggests that Gönnersdorf was occupied over an extended period of the year. The season of horse hunting was established by analysis of milk teeth to establish the age of the foals at death. For K I, K II, and K III, the season of death and hence human presence at Gönnersdorf extended from December/January until the beginning of the summer. An apparent cutoff here was perhaps when horses (and possibly reindeer) left the lowland Neuwied Basin for upland foaling and calving grounds, which may suggest a possible abandonment of the Gönnersdorf site during summer.

Other evidences such as tooth eruption patterns of reindeer and wolf, the presence of an otolith of a burbot (*Lota lota*), horse fetal bone at various stages of development, arguments for winter trapping of fox and possibly hare, and the probable seasonal presence of migratory birds provide support for a scenario of occupation over a longer period of time and through different seasons of the year. Altogether it suggests that coexistence by the inhabitants of K I, K II, and K III may have extended over a large part of the year.

The season of occupation for K IV and SW remains unknown due to both their generally

limited faunal evidence and absence of relevant information on the age at death of the horses.

Future Directions

Gönnersdorf must be seen as only one location in an extensively oriented land-use occupation strategy of highly mobile Magdalenian groups. That these mobile groups were also in a position to occupy specific localities intensively is shown by the vast amount of material accumulated at favored locations in the landscape such as Gönnersdorf. The observed intensity of settlement is probably a palimpsest of several occupations extending over several weeks to several months, representing repeated visits separated by periods of desertion.

The winter half of the year with the shortest hours of daylight and coldest temperatures is the time of year when the *temporary sedentism* reconstructed for Gönnersdorf would be the most appropriate survival strategy. It is possible that northern Magdalenian groups generally spent this time of the year in sheltered locations, such as the Rhine valley. While we have no certain information on the frequency of Magdalenian peoples' absence from the Central Rhineland, the available seasonal data strongly suggests that the season of their absence would have been the summer, while exogenous lithic materials and other materials give some indication of the distant regions visited at this time.

Finally, any analysis of complex Magdalenian sites must recognize their adaptability and variability. The sometimes very different structures at Gönnersdorf do not all represent the same range or intensity of activities, and it is quite probable that the function of a specific concentration changed dynamically through time according to several factors.

The apparently younger occupation of Gönnersdorf SW, with an associated fauna of elk and red deer, probably took place under quite different environmental factors than the main settlement phases of K I–K IV. The far more ephemeral evidence for human presence in SW possibly foreshadows the settlement patterns of the Federmessergruppen that will emerge during the younger wooded Allerød interstadial.

González, Alberto Rex

Javier Nastri
CONICET, Depto. de Cs. Nat. y Antropológicas + Fundación Azara, Universidad Maimónides/ Universidad de Buenos Aires, Buenos Aires, CABA, Argentina

Basic Biographical Information

Alberto Rex González (1918–2012) was a charismatic figure with the most profound influence on Argentine archaeology through the twentieth century. Born in Pergamino (Buenos Aires province), his introduction to archaeology came through an early reading of the work of Argentine naturalist Florentino Ameghino. This drove him from a young age to carry out excavations at different sites around the country.

After gaining his medical degree at the University of Cordoba (Argentina), he took archaeology courses at Columbia University (USA). In 1948, he began to work at the La Plata Museum (Argentina), and in 1953, he started to lecture at the University of Rosario. Three years later, he settled in Cordoba, where he was the Director of the university's Institute of Anthropology. In 1962, he returned to La Plata, now an established figure of Argentine archaeology, as a researcher at CONICET (the Argentine National Council for Scientific and Technical Research). In spite of all this, in 1976, he was fired from his academic position at the university, in the context of the terrorist military dictatorship which razed the country. Once democracy returned in 1983, he took up the role of lecturer at the University of Buenos Aires, where he was the Director of the Ethnographic Museum. Through his long career, he carried out numerous excavations, formed a considerable group of disciples, and published around 150 scientific and dissemination works. After retirement, he spent his last years organizing his archives in the city of La Plata.

Major Accomplishments

From the University of La Plata, at the end of the 1940s, he started a tenacious campaign to revive the practice of fieldwork. He also promoted a deeper temporal conception of the native occupation of Argentine territory: after obtaining the country's first radiocarbon dating of the deepest deposits of Inti Huasi cave (San Luis Province), he could reliably determine a minimum antiquity of 8000 years BP for the occupation of present Argentine territory, which constituted a true milestone in the history of archaeological investigations in Argentina.

Due to his initiatives, the first Argentine radiocarbon dating laboratory was set up, installed in the University of La Plata (Latyr). He also fostered the creation of CONICET, which is the country's main research institution which gathers the largest proportion of Argentina's professional archaeologists as full-time researchers.

His reformulation of the prehistory of northwestern Argentina, in the 1950s and 1960s, was based on the analysis of the burial contexts of the Muniz Barreto Collection held at the Museum of La Plata, which boasts an itemized record of its

documents. Calling on his detailed stylistic knowledge of the materials, and carrying out further excavations and radiocarbon dating, he proposed a *master sequence* of cultural development of the "agricultural ceramicist stage" of Hualfín Valley, which he extrapolated to the whole region denominated "valliserrana" (mountain-valley), greatly stimulating archaeological investigation.

One of his key publications, in collaboration with J. Pérez Gollán – *Indigenous Argentina. Eve of Conquest* (1972) – became a fundamental reference work about the prehistory of the Argentine territory.

With his 1974 book *Art, Structure, Archaeology*, he ventured into the terrain of the symbolic interpretation of aboriginal art, a subject that monopolized his interest during the latter years of his research career. In this work, influenced by the structuralism of Levi-Strauss, he identified the diverse mechanisms of physical and visual expression of Andean dualism in the material culture of the agricultural ceramic societies of Northwestern Argentine, as follows:

1. Feline-human mixed features (Fig. 1)
2. Multiple hybrid features
3. Human-feline attitudes mixed
4. Dual realistic images in the same piece
5. Duality of binary opposition as expression of other concepts
6. Duality in the same image (anatropical figures)
7. Duality by split representation (Fig. 2)
8. Duality by opposition of antipodean figures

His masterpiece is *Pre-Columbian Art of Argentina* (1977) in which he described and analyzed the plastic expressions of all the Indigenous cultures of Argentina, developing in particular the agricultural ceramicist stage in the northwest of the country with the greatest degree of detail achieved so far.

In *1992*, he published *The Metallic Plates of the Southern Andes*, an exhaustive compilation about the different types of objects manufactured in the South Andes area in pre-Columbian times.

With profuse iconography, these metallic plates (Fig. 3) still constitute a giant archaeological question mark, since it is very rare to find examples in properly documented archaeological contexts. In this work, González provided a first chronology based on elements of stylistic criteria and unfolded an original hermeneutic approach supported by historical and ethnographic sources.

González, Alberto Rex, Fig. 1 Ceramic piece from Aguada culture, taken by González as an example of the mixture of feline and human features (Taken from González 1974: Fig. 4.1)

González, Alberto Rex, Fig. 2 Example of two-sided representation in a Santa María funerary urn number 4534, La Plata Museum (González 1974: Fig. 2.3)

González, Alberto Rex, Fig. 3 Metallic plates from Río Lípez (Bolivia), from the corpus studied by González in his work *Las placas metálicas de los Andes del Sur* (Taken from Tomado de González 1992: plate 3)

At nearly 80 years old, by the end of the 1990s, he returned to fieldwork on the archaeological site *La Choya*, in the Province of Catamarca, revealing a new ceremonial center of the *La Aguada* culture. It is to the latter that he dedicated his last great work: *La Aguada Culture, Archaeology and Designs* (1998). Here, he provided the most complete image of the very cultural context that he himself had defined in the 1960s, and which constituted, after Max Uhle's synthesis in 1910, a fundamental watershed in the agro-ceramic cultural sequence of northwestern Argentina.

Google Earth Afghan Surveys

David C. Thomas
Department of Archaeology and History,
La Trobe University, Melbourne, VIC, Australia

Introduction and Definition

The development of "virtual globes," such as Google Earth and NASA's World Wind, represents "the most important development in aerial archaeology" for 35 years (Irwin Scollar, cited in Scollar and Palmer 2008: 15). "Virtual globes"

provide a user-friendly means of accessing geo-referenced (i.e., accurately located) satellite images of the world – there are no Google Earth or World Wind images per se, merely satellite images and aerial photographs available through these digital portals. "Virtual globes" are much more dynamic and interactive than more traditional, static photographic and cartographic representations of Earth, enabling viewers to move around, and zoom in and out, to determine what they want to investigate (Parcak 2009a: 3, 48). The costs involved are also low compared to purchasing commercially available satellite images and acquiring the geographical information systems (GIS) software and skills necessary to utilize these images – standard versions of Google Earth and World Wind are freely available to anyone with a high-speed Internet connection, while Google Earth Pro, which has some useful additional features but does not offer higher resolution or different images, is now also free.

World Wind consists of the Blue Marble, a true-color image of the entire Earth. When you zoom in closer, the "virtual globe" transforms into a seamless mosaic of Landsat 7 images, collected from 1999 to 2003. These images have been draped over a digital terrain model (DTM) derived from Shuttle Radar Topography Mission (SRTM) data to generate a relatively accurate three-dimensional model of the Earth's surface. World Wind also includes images with other color bands such as the infrared spectrum, which can be useful in identifying archaeological features (Parcak 2009a: 61), although the 15 m per pixel resolution of the Landsat images limits the value of World Wind to archaeologists interested in small sites and features.

In 2016, Google Earth upgraded its imagery to a seamless cloud-free mosaic of images from the Landsat 8 satellite and announced new processing techniques for sharper images – gone is the patchwork of geo-referenced high- and mid-resolution satellite images and aerial photographs which was, until recently, visible in some regions such as the northern Indian subcontinent and much of China and Southeast Asia.

The disappearance of the albeit patchy high-resolution satellite coverage formerly available through Google Earth presents one of the major constraints to its use by archaeologists. While densely populated areas, particularly in Western countries, tend to have higher-resolution coverage, due to user demand and the commercial synergies inherent in such projects, the coverage of sparsely populated, less developed countries such as Afghanistan is poorer. Only 7% of Afghanistan was covered by the relatively narrow strips of high-resolution images prior to an upgrade to 2.5 m spatial resolution SPOT imagery in June 2009 (Fig. 1). These high-resolution images, however, still amounted to a total area of 47,000 km^2 and formed the basis for detailed studies of known archaeological sites and under-explored areas by the Archaeological Sites of Afghanistan in Google Earth (ASAGE) project (Thomas et al. 2008; Thomas 2015; Thomas and Kidd 2017; see below). Unfortunately, although the upgrade to SPOT imagery, which was not announced in advance, resulted in a general improvement in the coverage of the country, many of the highest-resolution image strips are no longer available. This lack of transparency in the policies and timetabling of imagery upgrades is a major deficiency in Google Earth's program of updating satellite image coverage.

Despite its variable image resolutions, Google Earth has largely superseded World Wind due to the higher resolution of many of the images it uses. It has become an integral part of news broadcasts, television dramas, academic presentations, and "virtual" travel – over one billion copies of Google Earth software had been downloaded in 2011 since its launch in 2005. Users can visit specific places by searching Google Earth's database or simply explore whichever part of the globe interests them, unrestricted by national boundaries, topography, and no-fly zones.

The coordinates of sites can be uploaded from a spreadsheet using Google Earth Pro to create "placemarks." "Placemarks" can in turn be enriched with images, video clips, links to other Internet resources, and additional information via .kmz files posted on online bulletin boards such as History Illustrated (Ur 2006: 37). The extra measuring tools available in Google Earth Pro enable archaeologists to calculate the area of sites and

Google Earth Afghan Surveys, Fig. 1 Satellite images of Afghanistan, available through Google Earth prior to the 2009 upgrade to SPOT imagery; high-resolution strips are highlighted in *green* and ASAGE study areas outlined in *yellow*(Image GoogleEarth © 2007 DigitalGlobe © 2007 Europa Technologies Image © 2007 TerraMetrics)

their components, while existing maps and plans can be laid over the satellite images available through Google Earth to verify and improve site descriptions and integrate additional information such as geological data in the interpretative process (Fig. 2). Sketch plans of standing structures can also easily be generated over saved images using drawing software packages such as Adobe Illustrator.

The thousands of postings on the History Illustrated bulletin board highlight the popularity of the medium among "armchair archaeologists" and the plethora of unusual features which excite human curiosity (Fig. 3). The opportunities generated by this "democratization of satellite imagery," to use Stefan Geens' term, were soon recognized by several archaeologists, who saw the potential to increase the spatial area that can be studied and to engage with, and even enlist the help of, the general public (Beck 2006; Ur 2006; inter alia). Archaeologists, however, have largely failed to maximize the potential of Google Earth, primarily because most use Google Earth as a precursor to conducting fieldwork, rather than as a source of data for desk-based studies in its own right.

This oversight is starting to be addressed, as several recent innovative studies have demonstrated the value of Google Earth to archaeologists wishing to investigate regions which are difficult or impossible to reach for political, security, or logistical reasons. Archaeologists are in particular using Google Earth to revisit semiarid parts of North Africa, the Near East, and Central Asia, regions which were the foci of many of the pioneers of aerial archaeology such as Theodor Wiegand, Flt Lt Maitland, Father Poidebard, and Sir Aurel Stein (Kennedy and Bewley 2004:

Google Earth Afghan Surveys, Fig. 2 US Geological Survey map of northern Afghanistan laid over ASAGE study area 10 in Google Earth (Image GoogleEarth © 2011 Cnes/Spot Image Image © 2007 DigitalGlobe)

Google Earth Afghan Surveys, Fig. 3 An enigmatic "saucer-shaped" site (SA2_569) in the Rīgistān desert, Afghanistan – possibly a burial in a banked enclosure (Image GoogleEarth © 2008 DigitalGlobe © 2008 Europa Technologies)

51–52). The environmental conditions which facilitated previous aerial archaeology studies of these regions remain essentially the same – relatively low levels of natural vegetation and cloud cover, and the inhospitable terrain, result in optimum site preservation and visibility. The primary reason that these new studies using Google Earth are proving so productive is that much more of the landscape can now be studied systematically (Contreras and Brodie 2010: 101).

Reconnaissance of southern Libya as part of the Desert Migrations Project, for example, has revealed numerous "lost cities" built by the Garamantian civilization c. CE 1–500 (Sterry and Mattingly 2011). Visible structures include the mud-brick remains of fortified farms and village complexes, along with traces of cairn cemeteries, associated field systems, wells, and sophisticated irrigation systems. Over the border in Egypt, Sarah Parcak has used images available through Google Earth to gain "virtual" access to industrial compounds in the Markha Plain. This has enabled Parcak to identify a string of circular fortresses to the south of Tell Ras Budran, which are out of view of the main fortress but within fire−/smoke-signaling distance. These sites would probably have remained undiscovered and thus prone to unwitting destruction without the images available through Google Earth, because fieldwork is impossible in these restricted areas (Parcak 2009b: 363).

Further east in the Levant and Arabian Peninsula, David Kennedy's team has revealed much older and more extensive archaeological remains (Kennedy and Bishop 2011). The surviving desert kites (hunting traps), funerary/religious sites, and seasonal camps, many of which are virtually impossible to recognize at ground level without the benefit of an aerial perspective, indicate a prehistoric cultural continuum stretching across thousands of kilometers. The identification of nearly 2,000 sites in the 1,240 km^2 pilot study area illustrates both the potential of the technique and the rich pre-Islamic archaeological heritage of the region which has largely been ignored in the past – previous survey work has recorded just c. 1,800 sites throughout the whole of Saudi Arabia (Kennedy and Bishop 2011: 1292). Where available, however, declassified aerial photographs, such as those taken by the U-2 spy planes between 1958 and 1960, continue to offer higher-resolution images which provide a historical record of thousands of archaeological features, many of which have since been destroyed (Hammer and Lauricella 2017).

Elsewhere, the contemporary relevance of this form of archaeological research and the value of Google Earth's Historical Imagery View tool are evident in the documentation of the looting of archaeological sites in Jordan (Contreras and Brodie 2010) and Adrian Myers' study of Camp Delta (Guantánamo Bay, Cuba). The Historical Imagery View tool enables users to study successive images of the same place. By overlaying these images in a geographical information system and mapping changes in the site over time, Myers has been able to demonstrate both the rapid expansion and increasingly permanent nature of the prison facilities. As a result, Myers has been able to juxtapose the expansion of the USA's top security goal with official policy announcements relating to the site (Myers 2010: 464).

Few countries illustrate the vital importance of Google Earth to archaeologists better than Afghanistan, where the volatile security situation and unexploded ordnance render fieldwork impractical in many areas. Although the country was systematically photographed from the air during the 1960s, as part of a photogrammetric mapping initiative, these valuable archival images have since been lost. Satellite images, therefore, represent the major, largely untapped source of data for archaeological sites in the country and form the basis of two research projects: Cameron Petrie (2007) has used Google Earth to explore the archaeological sites positioned along ancient trade routes between Afghanistan and Pakistan, while Étienne de la Vaissière and his colleagues (2015) have used satellite imagery to reveal a Kushan military camp near Bactra. At the landscape level, the ASAGE project has sought to document a spatially and diachronically broader range of sites across selected study areas, while the Oriental Institute in Chicago's Afghan Mapping Project is now applying this research goal across the whole country (Franklin and Hammer 2018; Hammer 2016),

as is the Délégation archéologique française en Afghanistan (DAFA).

Key Issues/Current Debates

Only 10% of the sites listed in the archaeological gazetteer of Afghanistan (Ball 1982) have even rudimentary plans, so at the most basic level, Google Earth is being used to generate detailed sketch plans of numerous unplanned sites (Fig. 4; Thomas et al. 2008). Google Earth also provides valuable data on the relatively few sites which have been planned, such as the early Islamic (twelfth- to thirteenth-century CE) capital of Bust/Lashkar-i Bāzār. A French team led by Daniel Schlumberger conducted pioneering excavations and surveys at this sprawling site from 1949 to 1952. Despite their best efforts under difficult working conditions and with few resources, the art historian Terry Allen estimates that nearly 100 Ghaznavid/Ghūrid buildings, some standing two storeys high, survive at Bust, most of which have never been documented. The external walls of many of these structures, which are not marked on the French expedition's plans of the site, are clearly identifiable in Google Earth, while additional details can be collated for several of the other structures which were merely outlined (Thomas and Zipfel 2008). The archived satellite images also create benchmarks against which the impact of threats to archaeological sites, such as the encroachment of agriculture and urbanism, can be monitored over time.

In addition to providing valuable data on known sites in Afghanistan, Google Earth also provides a means of investigating unsurveyed areas. Given the limited opportunities for "ground-truthing" (i.e., checking results by site visits), this form of "remote" archaeological exploration benefits from the process of "visiting" and verifying known sites mentioned above – by exploring the known sites, researchers' eyes can become attuned to how archaeological features appear in Google Earth. This "virtual experience," as well as years of fieldwork experience in the region and a detailed appreciation of both landforms and archaeological site formation processes, is essential if previously undocumented sites are to be identified (and natural or modern features are not to be mistaken for archaeological sites).

A systematic approach to the study of images available through Google Earth, which by its very

Google Earth Afghan Surveys, Fig. 4 Sketch plan of the hitherto unplanned Ghaznavid site of Qal'a-i Hauz, derived from the imagery available through Google Earth (Image GoogleEarth ©2008 DigitalGlobe)

nature is highly time-consuming, wearying, and often tedious, is essential when they are being used for reconnaissance purposes. ASAGE researchers "zoomed in" to the 100–200 m scale, beyond which even high-resolution satellite images start to pixelate, and spent dozens of hours methodically scrolling up and down selected high-resolution study areas, "placemarking" ambiguous features (Thomas et al. 2008; Thomas and Kidd 2017). The most experienced field archaeologist on the project was assigned the task of cataloguing all the placemarked sites, in an effort to standardize site recognition and descriptions. This review process resulted in three quarters of the placemarks being dismissed as natural or too uncertain to document. Once catalogued, the images and data for the remaining placemarked sites were cross-checked by another archaeologist with firsthand knowledge of the region, so as to minimize errors, reduce subjectivity, and maximize standardization.

A degree of subjectivity is inherent in the process of cataloguing a placemark as an archaeological site, particularly when it is not possible to ground-truth the site and when the site's date and contemporaneity with other sites are difficult to determine. Subjectivity can be reduced by defining site types explicitly at the start of the project. Chronological parameters can be set by adopting the rolling 50-year date used by numerous heritage agencies around the world as the arbitrary division between "archaeological" sites and "modern" sites and comparing the satellite images in Google Earth with declassified CORONA images from the 1960s and 1970s. These images provide an effective terminus ante quem (date before which the sites must have formed) for most of the larger sites visible in both images and thus increase confidence that many of the other smaller sites identified in Google Earth are also premodern.

This relatively recent cutoff point differs from that adopted by Warwick Ball, who argues that if post-Tīmūrid (c. CE 1526) remains were included in his gazetteer "virtually every modern town and even many villages would qualify as a 'site'" (Ball 1982 I: 14). While Ball's reasoning is understandable given the practicalities of producing a gazetteer which already has over 2,000 sites in it, the relatively recent cultural heritage of Afghanistan is just as worthy of recognition, preservation, and protection as its older sites, as is the case elsewhere in the world.

Ten ASAGE study areas were selected in different environmental zones close to major early Islamic urban centers to investigate the use of different "marginal" landscapes by nomads and to test whether the methodology ASAGE has devised is applicable across the Afghan landscape and beyond. Only one of the ten study areas yielded more than 0.5 sites per km^2 (Table 1). Despite this apparently low success rate, 679 definite or probable archaeological sites were identified over an area of 2,680 km^2. These include

Google Earth Afghan Surveys, Table 1 Details of the ten ASAGE study areas in Afghanistan

Study area	Area (km^2)	Placemarks	Sites	Site density	Location	Date of image
SA1	312.5	163	55	0.18	N5 – south central desert around Qal'a-i Hauz	6/12/2004
SA2	273.5	579	118	0.43	N1 – primarily N of Arghandab	6/12/2004
SA3	240.5	599	171	0.71	N2 – south of Arghandab	6/12/2004

Google Earth Afghan Surveys, Fig. 5 SA2_101: *tepe* with towers guarding the entrance in the West; note the overlapping *kārīz* spoil heaps running to the north and south of the *tepe* (Image GoogleEarth © 2008 DigitalGlobe © 2008 Europa Technologies)

isolated nomad campsites and corrals, fortified dwellings and *tepe*s (occupation mounds, probably dating back several millennia), deserted villages, dams and reservoirs, and *kārīz* (underground water channels; Fig. 5). Prior to the study, only three archaeological sites were listed in the study areas.

The wealth of sites found in the Arghandāb river valley and Rīgistān desert (Thomas and Kidd 2017) contrasts with the much smaller numbers identified in the three study areas in the mountains of Ghūr province (SA6-8) and the two on the steppe in the north of Harāt province (SA9-10). The most obvious explanation is the differing intensities of use in the different environmental zones. Other factors, however, may have contributed to the reduced site numbers in these areas – summer campsites in the mountains are likely to be more dispersed and ephemeral than winter ones, while the harsh winters, which are accompanied by heavy snow falls and violent spring floods, may also have impacted on site preservation and visibility in the mountains of Ghūr.

The value of adopting a systematic approach to studying archaeological landscapes in Google Earth, therefore, extends beyond the numbers of sites identified. It permits an assessment of the significance of the distribution of sites in quantitative terms, relative to the types of sites found, different landforms covered, topographic features, and varying levels of preservation and visibility. The conclusions derived from such analyses have obvious implications for cultural heritage management and archaeological impact assessments.

Future Directions and Examples

The large number of sites in Afghanistan (and elsewhere) identified using Google Earth should not come as a surprise, despite the dearth of sites previously recorded in the study areas. Survey work in the 1960s and 1970s in the nearby deserts of Sīstān, the anecdotal reports from travelers in the region, and fieldwork in other semiarid regions of the Near East and Central Asia have demonstrated that deserts have been utilized by nomads for millennia and that their sites survive, despite often being ephemeral and difficult to date. The blanks on distribution maps are frequently due to a lack of investigation arising from Western preconceptions about "uninhabitable" semiarid regions rather than a lack of archaeological sites.

The primary value of the ASAGE research is as a basis for future fieldwork. The newly discovered sites need to be ground-truthed, both to establish the veracity of their identification and to collect datable ceramics from the surface. The detailed

sketch plans can be used by the relevant authorities and other archaeologists to develop site management plans, particularly where farmers are encroaching upon sites. The latest 4G mobile phone and iPad/tablet technology even raise the possibility of developing tourist itineraries and context-rich online resources at sites such as Ghazni, which was "Cultural City of the Islamic Civilization" for 2013 (Thomas 2015).

The archaeological potential of Google Earth is so vast that it cannot be exploited fully by a few academics alone. Much can be achieved by engaging with the sizable "armchair archaeologist" community and enlisting their assistance in exploring study areas and identifying sites, as Sarah Parcak is doing through her GlobalXplorer project. Engagement, however, is a two-way process and requires considerable commitment of time (in training, cross-checking, and providing feedback) and a willingness to communicate and share knowledge on the part of academics. Similarly, while much of Afghanistan remains a no-go zone for Westerners, it is imperative to share data with the National Afghan Institute of Archaeology and other relevant Afghan authorities, foreign archaeologists, NGOs and individuals, and sections of the military who are interested in discovering and protecting cultural heritage. The ease with which Google Earth data can be generated, exported, and exchanged provides a further example of how central this versatile medium will be to archaeological research for the foreseeable future.

Goose: Domestication

Kristiina Mannermaa
Department of Philosophy, History, Culture and Art Studies, University of Helsinki, Helsinki, Finland

Basic Species Information

Domestic geese descend from two wild species, the greylag, *Anser anser* (Linnaeus 1758), and the swan goose, *Anser cygnoides* (Linnaeus 1758) (Shi et al. 2006). The natural breeding range of the swan goose, the ancestor of the Chinese goose, is in Mongolia, North China, and southeastern Russia, and wintering areas are mainly in China. The breeding area of the greylag, the wild form of the domestic goose in Europe (European goose), covers Northern and Central Europe and Asia; wintering areas are in Southern Europe and Northern Africa. Two subspecies of the greylag are known, *A. a. anser* (western form) and *A. a. rubrirostris* (eastern form). Both *A. a. rubrirostris* and the European domestic goose have pink beaks, while *A. a. anser* has an orange beak. The pink beak indicates that the European domestic goose descends from the eastern form.

The two domesticated forms of geese, the European and the Chinese, are closely related. Both are widely spread in the world today, and they can have fertile offspring. Also wild forms, the greylag and the swan goose, can interbreed (Gray 1958). The Chinese goose grows larger than the European and has a longer neck; the male has a pronounced knob at the base of the beak. Both Chinese and European geese have white and gray breeds.

The Egyptian goose *Alopochen aegyptiaca* was kept by ancient Egyptians a long time before the greylags, but this species never became fully domesticated. One early use of domesticated geese has been for sacrifices (e.g., in Mesopotamia, Middle East, and classical Greece). Geese were probably sacred in Pre-Roman Britain (Zeuner 1963). Domestic geese were associated with religious symbolism in Roman times in Britain and Italy (Albarella 2005), and geese bones are regularly found in Iron Age burials in Northern and Central Europe. Over time, geese have provided meat, liver, and eggs. Wild or domestic goose was identified, for example, in Tutankhamun's tomb (c. 1330 BCE) among the remains of the funerary meal (Houlihan 1986). Romans and probably ancient Egyptians overfed geese in order to improve the flavor of the liver and meat. Perhaps, the most important material advantage of geese was the fine quality of feathers and down. Quill pens were used in medieval and historical times. Geese were respected house guards at least from Roman time onward.

It is currently not possible to date or locate when and where geese were kept for the first time, though in China, the goose was domesticated by ~1000 BCE and most likely earlier. The first introduction of the Chinese goose to Europe was in the eighteenth century.

Domestic geese are depicted on the walls of burial chambers in ancient Egypt c. 1400 BCE. Domestic geese appeared in ancient Greece by 700 BCE. Homer mentions white geese in the Odyssey c. 800–700 BCE, apparently meaning the domestic bird. Zeuner (1963) proposed that the domestication must have happened first in the breeding areas, where young birds were taken from nests and raised though the breeding distribution of the greylag does not cover Egypt.

The greylag may have been domesticated in many places at different times. Crossbreeding of domestic and wild forms has most likely happened often. For example, in Scotland and Fennoscandia, it had been common to take

young wild geese from the nests and raise these (Sirelius 1919). Geese probably belonging to the domestic form have been identified in samples dating from the Bronze Age (c. 1700–500 BCE) in Southern Sweden and Eastern Germany and Pre-Roman and Roman Iron Age (c. 400 BCE–CE 400) in Southern Sweden (Ericson and Tyrberg 2004), probably indicating a local domestication.

Based on size, domesticated geese were kept in Iron Age and Viking Age Denmark (c. CE 500–1000) and in Roman and Saxon Britain (c. CE 0–1000). However, according to archaeological materials, domestic geese became abundant only during medieval times in most of Europe (Reichstein and Pieper 1986; Yalden and Albarella 2009). In Western Russia the earliest morphologically identified domestic geese date to 500 BCE-300 CE, and genetically identified domestic geese to 10 CE (Middle Volga Region) (Honka et al. 2018). A sudden increase in the amount of goose bones and bones of young individuals in archaeological data can be interpreted as indirect evidence of the presence of the domesticated form.

Molecular studies of recent and archaeological specimens show a close genetic relationship between the different species of genus *Anser* (Barnes and Dobney 2000; Ruokonen et al. 2000; Shi et al. 2006). Separation between the domestic and wild *Anser* geese, or the eastern and western form of the greylag, by ancient DNA, has not yet been successful (e.g., Heikkinen 2017). Identification of plumage color by analysis of ancient DNA from the bone might in the future give good results in tracking the early domestication of geese.

All species in genus *Anser* are very similar in skeletal morphology, which makes species identification of archaeological bones difficult. Vague morphological differences occur in the cranium and sternum. In sternum, the keel is deeper in the domestic compared to the wild form (Yalden and Albarella 2009). However, these elements are rarely preserved in archaeological samples.

The earliest domestic geese were of similar size to their wild ancestors, making the bones of the earliest domestic geese indistinguishable from wild geese. Only few changes have occurred in the appearance of the European goose during domestication. As a consequence of selection, their size became larger and heavier, which led to a restricted ability to fly. Leg bones (probably not the tibiotarsus) of domesticated geese are stouter than those of wild forms because they carry the increased weight, and the wing bones are shorter and broader (Reichstein and Pieper 1986; Boessneck and Von den Driesch 1979).

The plumage color changed from gray to heterogeneous and finally to white in some domestic breeds. In about CE 27, Pliny the Elder writes about the value of down and meat from white geese, evidently pointing to the domestic form. The Romans knew several breeds of geese such as the small white German and the large white (Albarella 2005).

Gorodtsov, Vasily A.

Pavel F. Kuznetsov
Povolzhie's State Social-Humanitarian Academy, Samara, Russia

Basic Biographical Information

Vasily Alekseevich Gorodtsov (1860–1945) (Fig. 1) was an outstanding Russian archaeologist. He began the scientific work in the archival committee of Ryazan and Yaroslavl (1889–1899). During this period, Gorodtsov explored Neolithic settlements on the Oka River downs (the right feeder of the Volga River). In 1901, he was given a mission from the Moscow archaeological committee to lead excavations in the South of Russia. Over a period of six months, he excavated 107 barrows in the river Donets Basin (Kharkov Region). During this time, scientific excavation and describing the methodology of burial complexities was invented for the first time.

Gorodtsov, Vasily A., Fig. 1 Vasily Alekseevich Gorodtsov

From 1903 to 1929, Gorodtsov worked in the Historical Museum of Moscow. In 1905, his excavation report on the barrows was published. Four groups of burials were identified according to their stratigraphic horizons, all of them belonging to the second Bronze Age. There were three consequent Bronze Age cultures: pit-house, catacomb, and log house. Gorodtsov's division into periods took its rightful place in the history of European science in line with such systems as Montelius', Reineke, and Furumark.

Gorodstov had an active teaching profession also. From 1907–1914, he taught archaeology at the Moscow Archeological Institute and from 1915 to 1918, he taught at Shanyavsky National University. After 1918, he became a professor at Moscow State University. Sometime later, he became a professor at the Chernyshevsky Literature Philosophy and History University. Gorodstov was also a member of the Material Culture Institute of the ASUSSR. Many talented students followed him, the most famous of which is N. Y. Merpirt.

Major Accomplishments

V.A. Gorodtsov was the first person in 20 years to explore pit-houses of paleontological humans in

the East European territory (Timonov settlement, 1928). He classified Fatianovskaya, Panfilovskaya forest-steppe archaeological cultures. He researched sites of Scythian-plowmen and also artifacts of the Gorodetskaya and Diakovskaya cultures. Gorodtsov was the first archaeologist to organize large excavations in the Old Ryazan. He is the author of more than two hundred scientific works.

Gorodtsov's scientific works determined the direction of Russian archaeology for many years. This was characterized by the holistic and systematic approach of archaeological material classification. Gorodtsov's scientific work "typological methods in archaeology" was republished in the USA. V.A. Gorodtsov developed the historical approach to archaeology, which was initiated by his predecessor, Count A.S. Uvarov, and which is now typical of the Russian science. He invented a model concerning the establishment and the expansion of industrial farms in the Middle East, Balkans, and Central and East Europe. His publications prefigured Gordon Childe's diffusion theory in many respects. Gorodtsov's research regarding Eurasian cultures still plays a significant role in contemporary archaeology.

Basic Biographical Information

Richard Allen Gould was born in 1939, in Newton, Massachusetts, as an only child. His father served in the Pacific during WWII on the aircraft carrier USS *Yorktown* (CV-10) and, after the war, spent a career in higher education as President of Antioch College, Chancellor of the University of California at Santa Barbara, and, ultimately, Chancellor of the State University of New York (SUNY). During the war, his first-generation Finnish mother worked at a shipyard in Massachusetts, and Gould grew up in a bilingual household (Fig. 1).

Gould graduated with a B.A. (cum laude) in anthropology from Harvard University in 1961 and followed with a Ph.D. in anthropology from the University of California at Berkeley in 1965.

Gould's initial interest in archaeology was sparked by a meeting with the former Chair of the University of Chicago Department of Anthropology, Fay Cooper-Cole, who had retired to California and was a family friend. Through Cooper-Cole, Gould was introduced to one of Cole's former graduate students, Jessie Jennings, who was leading the southern section of the Glen Canyon Project – a vast public archaeology undertaking that was to catalogue and excavate key sites along the Colorado River that would be submerged by the construction of Glen Canyon Dam. Gould worked under the exacting tutelage of Jennings during field

seasons in 1961–1962 and came to appreciate the value of science and intellectual rigor as applied to archaeological work.

While at Berkeley, Gould wrote a Ph.D. thesis on Northern California Tolowa ethnoarchaeology. The work addressed questions of cultural continuity and change that were tested via excavations at the Point Saint George Site. Gould's thesis advisor, John Rowe, was a prominent Peruvian scholar, and though he did not become an Inca specialist, Gould was drawn to Rowe by his expertise in ceramic analysis and culture history which he has applied to other areas throughout his professional life.

Subsequent to his graduate work in California, Gould and his wife Elizabeth (Betsy) did groundbreaking work in ethnoarchaeology with the Aboriginal people of the Western Australian Desert. Drawing on past experiences, the Goulds proposed the concept of a Western Desert Culture – a discernible amalgamation of the ideas of cultural continuity drawn from John Rowe coupled to the culture area theories of Jessie Jennings.

After work in Western Australia, Gould looked to his mother's homeland of Finland where he studied the historical processes of farm abandonment and the material residues that were left behind as Finish families reacted to varying degrees of socioeconomic stress after the Russo-Finnish War and WWII.

In 1977 while on sabbatical to Cambridge University to work on his book *Living Archaeology*, Gould met maritime archaeologist Keith Muckelroy. Muckelroy sparked a long-term interest in the subject of underwater archaeology in Gould, and in 1981 he chaired a School of American Research Seminar dedicated to the subject. From this seminar came the highly regarded book *Shipwreck Anthropology*, one of the first volumes to advocate for an explicitly anthropological approach to underwater archaeology. The seminar began a long, productive professional relationship between Gould and National Park Service underwater archaeologists Daniel Lenihan, Larry Murphy, Matthew Russell, and David Conlin. Following the seminar, Gould expanded his research interests to include underwater work in Dry Tortugas, Florida, and Bermuda.

After the September 11, 2001 terrorist attacks, Gould realized that the techniques of archaeology could provide insights into mass-casualty events and bring closure to the families of those who died. Gould's World Trade Center work was followed, in 2003, by a much larger examination of a tragic fire at "The Station" nightclub in Warwick Rhode Island – this work tied in with his commitment to a "knowable past" and an empirical approach in line with the standards of modern crime-scene forensics.

Gould retired from his position in the Department of Anthropology at Brown University in 2009 and currently lives in Honolulu, Hawaii, with his sweetheart and wife of 50 years Betsy Gould (neé Barber).

Major Accomplishments

After completing his Ph.D. in Anthropology at Berkeley, Gould embarked on a diverse

examination of different subjects, all tied together by the common thread of human cultural and behavioral adaptations to stress, risk, conflict, and uncertainty (http://philosopedia.org/index.php/Richard_A._Gould). Gould's career blossomed during the transition in American archaeology from cultural-historical particularism to the scientific/ecological focus of the New Archaeology in the late 1960s and 1970s, and he remained heavily involved in the field during the period of paradigmatic confrontation between Post-Processual and Processual archaeology in the late 1980s and 1990s.

Gould's definition of "culture" shades closely to a "bio-cultural" mechanism of adaptation that combines elements of both biological and non-biological aspects of human experience as opposed to an ideational notion of culture defined as a negotiated system of symbols. As such this sometimes put him at odds with archaeologists of the Post-Processual movement as it moved into maturity in the 1990s.

Gould's writings are fundamentally scientific and carry a theme of a "real past" that is knowable in some of its facets via the careful application of science and the scientific method. Gould's approach has been to apply standards of evidence akin to courtroom testimony (i.e., empiricism, logical connection, minimal assumptions, and rigorously argued linkages between the observed material and inferred behavioral causes) to the results of his research. His mass-casualty work came as a result of his emphasis on science and the notion that in some instances there is a single answer that adheres most closely to the facts and is at least "provisionally true." Gould privileges statements about the past that carry with them minimal assumptions, yet he has also been able to ague from particular instances such as the shipwrecks of the Spanish Armada and the salvage of WWII aircraft during the Battle of Britain towards more generalized statements of human behavior as related to risk, stress, and conflict that have broad applicability over time and space.

Gould argues that the past is knowable with varying degrees of certainty and also notes that a large amount of human behavior, even in some surprising instances, can be linked to adaptive responses to the environment. In this he defines "environment" as encompassing both the physical environment and also the larger socioeconomic forces that shaped human decisions in the past. He is a strong proponent of a stepwise approach to the study of cultural adaptation that encompasses multiple feedback loops combining a systemic relationship of both the ideational and biological aspects of human experience. In this Gould advocates for the use of both "emic" (i.e., internal, socially constructed categories of thought and meaning such as local religion) and "etic" (i.e., external categories of thought and meaning such as the application of the Western scientific method).

Graffiti Archaeology

Jordan Ralph
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Graffiti is an important source of material evidence through which archaeologists can learn about cultural identities and ideas. The tradition of graffiti goes back to ancient Greece and Rome, if not earlier (Baird and Taylor 2010). One of the renowned characteristics of Pompeii and Herculaneum is the wealth of political slogans and bawdy statements that are inscribed on the walls of buildings, both inside and outside (Benefiel 2010; UNESCO 2013). In contemporary societies, graffiti is widely perceived as undesirable and labeled as "vandalism" and often connected with feelings of adrenaline (O'Doherty 2012).

Archaeologists investigate the nexus of technique, form, and content of this visual culture to extract uncensored, uninstitutionalized information about attitudes toward social, political, religious, and ideological issues. Graffiti is a continuation of the landscape-marking and mark-making communication practices that have been used by humans for at least 40,000 years. While rock art receives much academic interest owing to its ability to reveal a myriad of information about past societies, economies, material culture, and ideologies (McDonald 2012), the same can be said of classical, medieval, and historical colonial, military, and convict graffiti. Though this entry focuses on contemporary graffiti, the issues discussed are relevant to classical, medieval, and historical graffiti.

Definition

Graffiti, the plural of graffito, comes from the Italian word *graffiare*, meaning "to scratch" and is used to refer to human-made markings in the public domain. The term is widely used to describe markings that are unauthorized or illegal and can include expressions in both two- and three-dimensions. Certainly, graffiti is generally conceived as illegal behavior (e.g., Fig. 1); however, not all types of graffiti are illegal. Graffiti becomes illegal and/or vandalism when the author does not have a legal right to be making their mark on the surface they are marking.

Graffiti can be defined as a form of visual communication and intended human-made marking that occurs publicly on any fixed surface in natural and built landscapes. Put simply, graffiti is communication through landscape-marking, and is inclusive of a wide range of forms, such as regulated traffic signs, public murals, advertising, and street art. This definition maintains a degree of fluidity and flexibility and is consistent with archaeological approaches to rock art style as a means of communication (Wobst 1977; McDonald 2012). From this viewpoint, graffiti encompasses all public visual communication, regardless of authorship, form, material, technique, message, legality, and social and cultural acceptances.

Key Issues and Current Debates

One key issue under current debate concerns what actually constitutes graffiti. Daniell (2011: 455) explains that graffiti comprised "essentially handwriting or hand-drawn designs" until the late 1960s and early 1970s, when "tagging" became popular and urban graffiti became "larger and more colourful and included designs, writing and pictures"; this change came about due to the availability of new techniques and implements, such as aerosol spray cans. Macdonald (2001: 2–3) argued that the contemporary practice of graffiti is "far from mindless or senseless and that there is always a purpose behind [its] production". Frederick (2009: 212) agreed, stating that graffiti is "a mode of expression and communication which comprises a vast array of media, technique, subject matter, form and meanings" and that a common feature of most graffiti is that comprises "text and/or images that [are] made in shared spaces where it is viewed publicly, be that a privately owned building, public transport, or an alleyway" (Frederick 2009: 212). David and Wilson (2002: 43) say that graffiti:

> . . . has a more pointed definition, referring to unsolicited inscriptions in public spaces. As a form of inscription usually practiced outside the censoring arm of the power elite, graffiti confronts and contradicts the ordered and ordering space of institutionalised life. Thus by definition, graffiti is imbued with a polluting and vandalistic quality irrespective of its decorative potential. It threatens the status quo not just because of the words or images written, but by the fact that its execution in public spaces lies outside the control of existing social forces.

Daniell (2011) argues that our understanding of contemporary graffiti should be informed by contemporary issues, such as legality, regulation, control, and resistance; however, using a similar approach toward non-contemporary graffiti is problematic because those markings were created under different legal, political, and social circumstances (Daniell 2011: 458, 462).

Several archaeological studies of graffiti have been undertaken across the globe and the following paragraphs are examples of some of the recent graffiti archaeology projects that have been undertaken around the world. In the United Kingdom, Graves-Brown and Schofield (2011) studied graffiti found on the interior walls of an apartment at 6, Denmark Street, London. This location was once occupied by members of the punk band, Sex Pistols, and the study mainly focused on caricatures of band members drawn by Sex Pistols lead singer, John Lydon. Graves-Brown and Schofield (2011: 1398) questioned whether heritage conservation of this location might betray the "spirit of punk and rock music more generally," and were

criticized in mainstream media for suggesting this site should attract the same level of significance and attention as a site from the distant past. One of the major messages to come out of Graves-Brown and Schofield's (2011) article, and one that was missed in the media, is the issue of cultural heritage management, preservation, and conservation in light of intersecting and even counteracting cultural needs:

> In case readers are wondering whether this paper is written tongue in cheek — or with tongue sticking out — it is worth recalling that modern archaeology includes recent periods in its remit, and uses recent materiality to help understand more ancient times as well as a critique on modernity itself.

Oliver and Neal (2010: 15) focused on tree carvings throughout their study of contemporary graffiti in the UK, and argue that "archaeologists and others have begun to turn their attention away from symbols of authority and towards the daubed, painted and scratched writings of the disadvantaged, the excluded or the subversive in society" because these are the stories that are not likely to be discovered in other media. Such an approach allows people to understand the ways in which visitors and inhabitants actively use the space and landscapes available to them, and helps people to acknowledge that these places are not "ageless, static or just plain dull" (Oliver and Neal 2010: 20).

In continental Europe, Merrill and Hack (2013) investigated Soviet graffiti at a former military base in Germany. Merrill and Hack (2013: 101) argued that it is archaeologically important for "graffiti and other forms of what is traditionally considered vandalism to contribute to the cultural significance and interpretation of heritage sites." This study includes an argument similar to that of Oliver and Neal (2010) that graffiti can highlight and reveal information about people, places, and events that would otherwise remain unknown or lost. It is suggested that the Soviet graffiti adds to, rather than reduces, the cultural significance of the heritage site, and can be used as a system of interpretation (Merrill and Hack 2013).

South African archaeologist Sven Ouzman (2010: 1) examined the implications of approaching historic and contemporary graffiti as a "multi-sensorial" artifact comprising blends of "crime, art, corporate co-option, and historic witness" to understand post-Apartheid South Africa. Our understanding of what constitutes "rock art" and what constitutes "graffiti" is questioned by Ouzman (2010: 17) upon his discussion about attitudes toward inscriptions made by soldiers from the Boer War, because, he argues, some people do not like these inscriptions being referred to as rock art, despite having striking similarities; Ouzman (2010: 18) asks: "is this because 'rock art' is perceived to reside unthreateningly in the past and 'graffiti' is an easy to ignore pollutant?"

In Australia, Frederick (2009) considered the link between ancient Aboriginal Australian rock art and contemporary urban graffiti in Perth. Frederick (2009: 210) used an archaeological approach to contemporary graffiti to identify the significance of contemporary graffiti as an artifact. This study (2009: 229) has implications that may lead to a more informed approach to rock art research, in particular, the suppositions that rock art researchers make about the images depicted in rock art. For example, images and slogans depicted in contemporary graffiti can be sanctioned by some from the community, while at the same time be unsanctioned by others. Interpretations of contemporary graffiti data are marred by our separation from insight into the graffiti writer's intention and motivation; this is equally so for rock art data. Frederick (2009: 231) argues that there is no single conclusion that can be drawn from contemporary graffiti data, and rock art researchers should not be aiming for a conclusive interpretation of rock art data.

Ralph (2012) conducted research into contemporary Indigenous graffiti in the Jawoyn Aboriginal communities in the Northern Territory, Australia. He developed a theoretical model to underpin a more nuanced understanding of contemporary landscape-markings, drawing upon actor-network theory, in which a "disparate family of material-semiotic tools, sensibilities and methods for analysis that treat everything in the social and natural worlds as a continuously generated effect of the webs of relations within which they are located" (Law 2007: 2). Accordingly,

communication through landscape-marking is interpreted as existing in a web of interdependent relationships which are embedded in empirical, materially grounded practices (Callon 2006). Actors in this web include governments, communities, and individuals who communicate their own experiences and agendas through the action of landscape-marking. As Couldry (2004: 1) points out, both human and nonhuman entities within these webs "acquire power through the number, extensiveness and stability of the connections routed through them." In Aboriginal communities in Northern Australia, Ralph (2012) found that graffiti serves the intra-group purpose of communication between community members, rather than the intergroup purpose of propagating political and social commentary (e.g., Fig. 2). He argued that the graffiti was more closely aligned to the ongoing cultural tradition of rock art production and landscape-marking, than to the contemporary graffiti expressions often found in urban settings (e.g., Fig. 3).

Each of the above studies has three common themes. Firstly, the authors acknowledge that graffiti in contemporary societies is often seen as vandalism, and they each attempt to redress that point of view, for example, Oliver and Neal (2010) and Merrill and Hack (2013) who claim that graffiti archaeology has the potential to uncover information about people whose stories may not be found elsewhere. The archaeology of graffiti, while by no means a new area of archaeological inquiry, is growing at a rapid rate. Prior to the early twenty-first century, very little archaeological research was conducted on contemporary, or even historical, graffiti. During the early twenty-first century, graffiti archaeology has become a considerably sized stream of the archaeological discipline, which involves a number of researchers from across the globe, particularly in the United Kingdom, continental Europe, Africa, and Australia. In saying this, and coupled with contemporary viewpoints toward graffiti, the second common theme of the above studies is that graffiti archaeologists tend to argue for the legitimacy of their work; for example, Graves-Brown and Schofield (2011) and Oliver and Neal (2010). Finally, many archaeologies of graffiti attempt to situate the contemporary practice of graffiti as part of an ancient, continuing visual culture that consists of vital social meaning and information, rather than a clandestine, unsavory, and meaningless act, for example (Frederick 2009; Ouzman 2010; Graves-Brown and Schofield 2011; Ralph 2012).

In 2013, the state of graffiti archaeology intimates that this stream of archaeology will continue to grow in both scholarship and interest. This is due, in part, to the capacity for up-and-coming archaeologists to explore "new ground" in

Graffiti Archaeology, Fig. 2 High-density minuscule graffiti on a road sign, community meeting area, Barunga region, Northern Territory, Australia, 2012. The location, size, and density of graffiti demonstrate that this is a form of intra-group communication

Graffiti Archaeology, Fig. 3 "Tag" graffiti, inscribed over public mural, Venice Beach, California, USA, 2011

these relatively under-examined contemporary, historical, medieval, and ancient material practices, but more so because the purpose of archaeology and archaeological research is to learn about past human behavior. As with other archaeological materials, graffiti allows archaeologists to understand the cultural identities and behaviors of humans in the past.
